## SIMULATION DETAILS

The details of all simulation cases are summarized in Table I and II. Here  $N$  denotes the simulation resolution, and  $R_L^-$  the generalized Reynolds number defined in (6). The Taylor-scale Reynolds number  $R_\lambda$  and the turbulent Mach number  $M_t$  are defined as

$$R_\lambda = \text{Re} \frac{\langle \rho \rangle u' \lambda}{\langle \mu \rangle}, \quad M_t = \text{M} \frac{\sqrt{3} u'}{\langle T^{1/2} \rangle}. \quad (1)$$

$\delta_c = u'_c/u'$  denotes the compressibility parameter, and  $k_{\max} = N/2$  the largest resolved wave number in simulations. The kinetic and magnetic Kolmogorov length-scales are defined as

$$\eta_u = \text{Re}^{-3/4} \left( \langle \nu \rangle^3 / \varepsilon_k \right)^{1/4}, \quad \eta_m = \text{Re}_m^{-3/4} \left( \langle \nu \rangle^3 / \varepsilon_m \right)^{1/4}. \quad (2)$$

$L_u$  denotes the kinetic integral length,  $\theta_{\text{rms}}$ ,  $\omega_{\text{rms}}$  and  $j_{\text{rms}}$  the rms values of dilatation field  $\theta = \nabla \cdot \mathbf{u}$ , vorticity field  $\boldsymbol{\omega} = \nabla \times \mathbf{u}$  and magnetic current density  $\mathbf{j} = \nabla \times \mathbf{b}$ , respectively. The parameter  $\rho_c = 2 \langle \mathbf{u} \cdot \mathbf{b} \rangle / \langle \mathbf{u}^2 + \mathbf{b}^2 \rangle$  denotes the normalized cross helicity, while  $H_m = \langle \mathbf{a} \cdot \mathbf{b} \rangle$  the magnetic helicity.

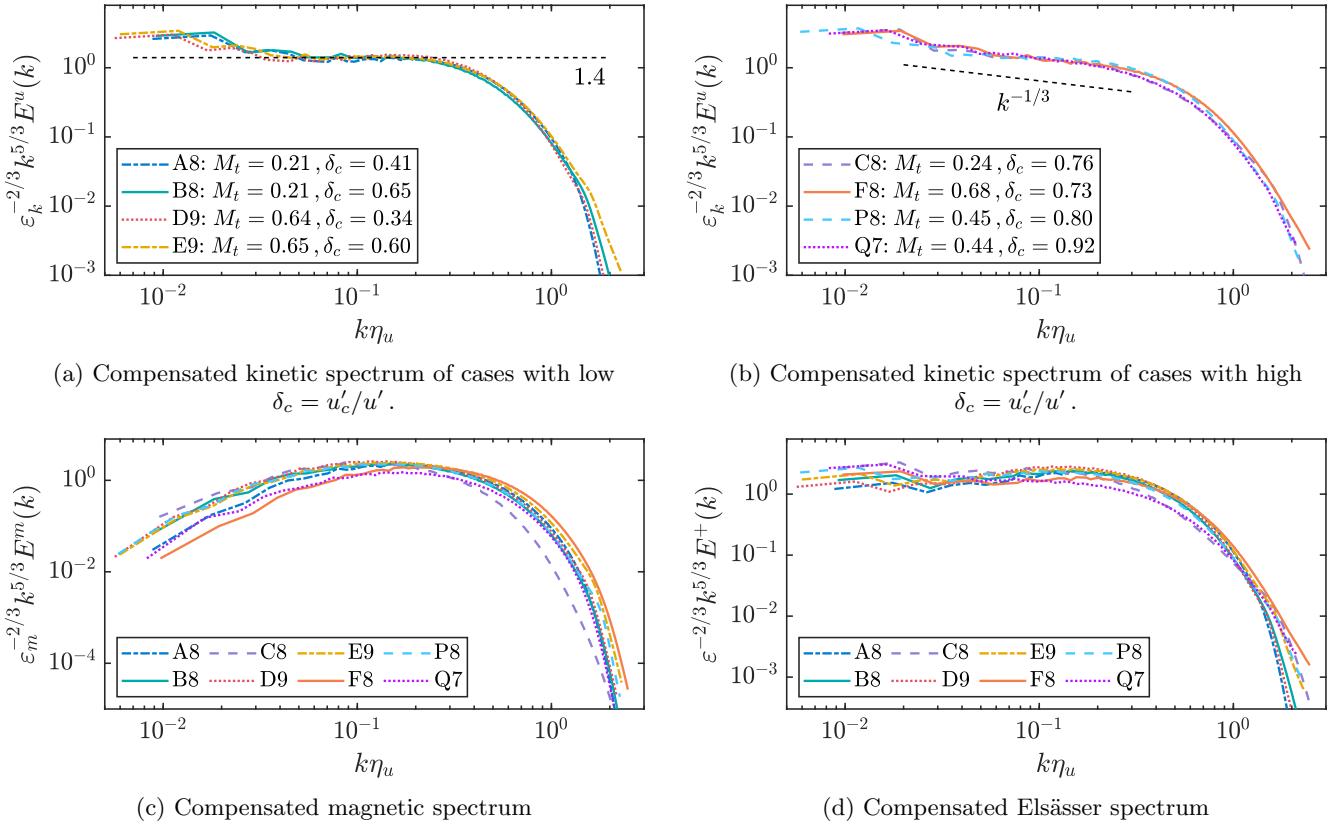

FIG. 1: Compensated spectrum of selective DNS cases.

## THE SPECTRUM OF SELECTIVE SIMULATION CASES

The compensated kinetic spectrum  $\varepsilon_k^{-2/3} k^{5/3} E^u(k)$ , magnetic spectrum  $\varepsilon_m^{-2/3} k^{5/3} E^m(k)$  and Elsässer spectrum  $\varepsilon_k^{-2/3} k^{5/3} E^+(k)$  of selected simulation cases are plotted in Fig. 1. Here  $\varepsilon_k, \varepsilon_m$  are the kinetic and magnetic dissipation rate (per unit mass):

$$\varepsilon_k = \text{Re}^{-1} \langle \sigma_{ij} S_{ij} / \rho \rangle, \quad \varepsilon_m = \text{Re}_m^{-1} \langle \eta \mathbf{j}^2 / \rho \rangle, \quad (3)$$

and  $\varepsilon = \varepsilon_k + \varepsilon_m$  denotes the total dissipation.  $E^u(k), E^m(k), E^+(k)$  denote the spectrum of velocity field  $\mathbf{u}$ , magnetic field  $\mathbf{b}$ , and Elsässer variable  $\mathbf{z}_+ = \mathbf{u} + \mathbf{b}/\sqrt{\rho}$  respectively, and satisfy

$$\int_0^\infty E^u(k) dk = \frac{1}{2} \langle \mathbf{u}^2 \rangle, \quad \int_0^\infty E^m(k) dk = \frac{1}{2} \langle \mathbf{b}^2 \rangle, \quad \int_0^\infty E^+(k) dk = \frac{1}{2} \langle \mathbf{z}_+^2 \rangle. \quad (4)$$

For cases with low to moderate compressibility (see Fig. 1(a)), the solenoidal field dominates and thus kinetic spectrum fits well with the classical  $k^{-5/3}$  power law, with the Kolmogorov constant  $C_K \approx 1.4$ . As the flow compressibility increases such that  $\delta_c > 0.7$ , the  $E^u(k) \sim k^{-2}$  trend appears (see Fig. 1(b)), due to the formation of large-scale shock waves [1, 2]. The different power law exponents of kinetic spectrum  $E^u(k)$  suggests that the large-scale force can strongly influence the energy cascade behavior, and implies the nonuniversality of compressible MHD turbulence state associated with the dimensionless parameter  $\delta_c = u'_c/u'$ . Additionally, the magnetic spectrum  $E^m(k)$  exhibits the  $\sim k^{-5/3}$  scaling for all cases studied here, indicating the flow compressibility has little impact on the magnetic energy cascade. As mentioned in the Letter, the magnetic field is mainly dominated by the strong turbulent shear motions at small scales, which can also be observed in Fig. 1(c), in which the compensated spectrum reaches its maximum at moderate wave-numbers.

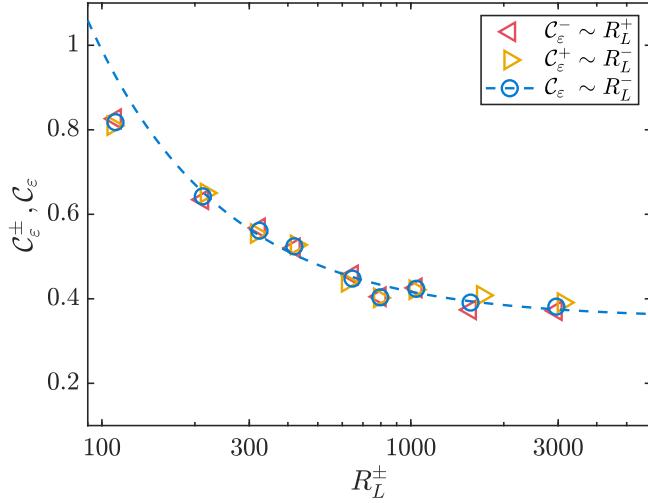

FIG. 2: The normalized dissipation rate versus the generalized large-scale Reynolds number for data from simulation series E. The dashed line indicates the fitting model described in Eq. (8).

### THE CHOICE OF $\mathcal{C}_\varepsilon^+$ OR $\mathcal{C}_\varepsilon^-$

In this study, the cross helicity  $H_c = \langle \mathbf{u} \cdot \mathbf{b} \rangle$  and the corresponding spectrum  $E_c(\mathbf{k}) = \langle \mathbf{u}^*(\mathbf{k}) \cdot \mathbf{b}(\mathbf{k}) \rangle$  remain small in all simulation cases. Hence we have

$$\langle (\mathbf{z}^+)^2 \rangle = \langle (\mathbf{z}^-)^2 \rangle, \quad \int_0^\infty k^{-1} E^+(k) dk = \int_0^\infty k^{-1} E^-(k) dk. \quad (5)$$

Recall that the key quantities about dissipative anomaly are defined as

$$\mathcal{C}_\varepsilon^\pm = \frac{\varepsilon L_\pm}{(Z_\pm)^2 Z_\mp}, \quad \mathcal{C}_\varepsilon = \frac{1}{2} (\mathcal{C}_\varepsilon^+ + \mathcal{C}_\varepsilon^-), \quad R_L^\pm = \frac{\langle \rho \rangle Z_\pm L_\mp}{\langle \mu \rangle}, \quad (6)$$

where  $Z_\pm$  and  $L_\pm$  denote the rms values and the integral length-scales of the Elsässer variables  $\mathbf{z}_\pm$ . Therefore, in the zero cross helicity cases one should expect that

$$Z_+ = Z_-, \quad L_+ = L_- \implies R_L^+ = R_L^-, \quad \mathcal{C}_\varepsilon = \mathcal{C}_\varepsilon^+ = \mathcal{C}_\varepsilon^-, \quad (7)$$

and the following model between  $\mathcal{C}_\varepsilon$  and  $R_L^-$

$$\mathcal{C}_\varepsilon = \mathcal{C}_{\varepsilon,\infty} + \frac{\mathcal{D}}{R_L^-} + O[(R_L^-)^{-2}] \quad (8)$$

is adequate to explore the dissipative anomaly phenomenon.

Fig. 2 depicts the relation between the normalized dissipation rate and the generalized large-scale Reynolds number for DNS series E. Here the relation of  $\mathcal{C}_\varepsilon^-$  versus  $R_L^+$ ,  $\mathcal{C}_\varepsilon^+$  versus  $R_L^-$ , and  $\mathcal{C}_\varepsilon$  versus  $R_L^-$  are all scattered. The fitting curve of  $\mathcal{C}_\varepsilon$  versus  $R_L^-$  using model (8) is plotted as well. Clearly, the specific choice of  $\mathcal{C}_\varepsilon^+(\mathcal{C}_\varepsilon^-)$  and  $R_L^-(R_L^+)$  has little impact on the results.

### THE CHOICE OF FITTING MODELS

As outlined in the manuscript and suggested by prior studies [3, 4], the following two kinds of models both can be used to quantify the relation between the normalized dissipation rate  $\mathcal{C}_\varepsilon$  and generalized Reynolds number  $R_L^-$ .

- model-1: Utilizing the first order model

$$\mathcal{C}_\varepsilon = \mathcal{C}_{\varepsilon,\infty} + \frac{\mathcal{D}}{R_L^-},$$

and fitting data points with moderate to large Reynolds numbers ( $R_L^- \geq 150$ ).

TABLE III: The estimate values and standard errors of fitting model coefficients.

| Series | model   | R2    | $\mathcal{C}_{\varepsilon,\infty}$ | $\sigma_C$ | $\mathcal{D}$ | $\sigma_D$ | $\mathcal{F}$ | $\sigma_F$ |

- model-2: Employing the second order model

$$\mathcal{C}_\varepsilon = \mathcal{C}_{\varepsilon,\infty} + \frac{\mathcal{D}}{R_L^-} + \frac{\mathcal{F}}{(R_L^-)^2},$$

and incorporating all DNS cases, including those with low Reynolds numbers, for fitting.

To compare these models and investigate the influence of the higher-order term  $(R_L^-)^{-2}$  on the asymptotic dissipation rate  $\mathcal{C}_{\varepsilon,\infty}$ , we performed fitting procedures for both models using data from simulation series A-F. (Series P and Q do not involve DNS cases with low Reynolds number, hence are not included in the comparisons).

The estimated model coefficients  $\mathcal{C}_{\varepsilon,\infty}, \mathcal{D}, \mathcal{F}$  are summarized in Table III. The table also includes corresponding standard errors  $\sigma_C, \sigma_D, \sigma_F$ , and the coefficient of determination R2 to evaluate the goodness of fit. Remarkably, R2 values consistently surpass 0.91 (with most cases exceeding 0.96), while the ratios  $\sigma_C/\mathcal{C}_{\varepsilon,\infty}$  and  $\sigma_D/\mathcal{D}$  remain small, signifying excellent fits and the ability of both models to describe the  $\mathcal{C}_\varepsilon \sim R_L^-$  relationship effectively. Furthermore, the close agreement between estimated values of  $\mathcal{C}_{\varepsilon,\infty}$  and  $\mathcal{D}$  from both models suggests that considering first-order terms in  $R_L^-$  suffices for this study. Notably, the estimated values of  $\mathcal{F}$  in the second-order model are consistently negative, in line with findings from incompressible MHD turbulence studies [4].

Figure 3 illustrates the data points alongside the two fitting curves, indicating remarkable alignment when  $R_L^- \geq 200$ . This convergence indicates that both models yield similar predictions for the asymptotic dissipation rate  $\mathcal{C}_{\varepsilon,\infty}$  again.

In summary, above results and discussions underline the capability of both models to elucidate the relationship between the normalized dissipation rate  $\mathcal{C}_\varepsilon$  and generalized large-scale Reynolds number  $R_L^-$  in compressible MHD turbulence, and the suitability of using first order model for subsequent studies detailed in the manuscript.
