Figure S11: Safety data – absence of local reactions during OIT for cows' milk allergy

First author, year,	Immunoglobulin measured	Method of	Time parameters	Findings
country		measurement		
RCTs				
Burks, 2012; USA	Specific IgE IgG4 (egg-specific)	Serum egg-specific IgE and IgG4 were measured with the use of the ImmunoCAP 100 (Thermo Fisher Scientific).	Baseline to month 10, 22 and 24	At 10 months, specific IgE levels were lower in children who were successfully desensitized at 22 months than in those who were not (p=0.02 and p=0.04, respectively) Median IgG4 levels at 10 months were higher in children who were desensitized at 10 months (p=0.0007), those who were desensitized at 22 months (p=0.005), and those who had sustained unresponsiveness at 24 months (p=0.02), as compared with children who did not pass the oral food challenge at these time points.
Caminiti, 2009; Italy	Specific IgE		Before the beginning of oral desensitization.	Measured only for the purpose of diagnosing CMA.
Enrique, 2005; Spain Enrique, 2008^	Specific IgE IgG4 (hazelnut specific)	Specific IgE against hazelnut was measured by an enzyme allergosorbent test.	Blood samples taken before treatment for in vitro studies. Blood samples were again drawn for in vitro studies 8-12 weeks later (at time of final DBPCFC).	Specific IgE showed no significant changes before and after SLIT in both groups. IgG4 levels: no statistical significance was found between the studied groups. However, there was an increase in the mean IgG4 levels in the active group (from 7.34 allergen units (AU)/mL to 9.84 AU/mL, P < 0.05).
Fernandez- Rivas, 2009; Spain	Specific IgE IgG4 (specific to Pru p 3)	Specific IgE to rPru p 3 was determined by the ADVIA Centaur	Serum samples were collected at T0, T1 and T6, and processed	Specific IgE showed a significant increase both in the active ( $P < 0.001$ ) and placebo ( $P = 0.025$ ) groups, although the increase

# Appendix 6: Immunological assessment and outcomes (immunoglobulin analysis)

First author, year,	Immunoglobulin measured	Method of	Time parameters	Findings
country		measurement		
Garcia, 2010^		platform and specific IgG4 to nPru p 3 by means of ELISA.	together at the end of the study by an investigator blinded to the treatment. (T0 = before treatment, T1= after 1 month of treatment, T6 = after 6 months of treatment).	remained only significant at T6 in the former (active 4.23, $P < 0.001$ ; placebo 4.04, $P = 0.079$ , T-test). No significant inter-group differences were observed ( $P = 0.456$ ). None of the patients with negative IgE to rPru p 3 at T0 converted to positive at T1 or T6. IgG4 to nPru p 3 showed a different evolution between groups ( $P = 0.022$ ) with a significant increase in the active arm ( $P = 0.007$ ) not observed in the placebo one ( $P = 0.185$ ).
Fleischer, 2013; USA	Specific IgE IgG4 (peanut specific)	Serum egg-specific IgE and IgG4 were measured with the use of the ImmunoCAP 100 (Thermo Fisher Scientific).	Serum was obtained at baseline, at weeks 29, 44 and 68	Specific IgE week 44 peanut –specific IgE 35.8 (3.3 to 75.0) in SLIT versus 20.1 (4.1 to 80.3) in placebo (NS). Increase between baseline and week 44 in SLIT. IgG4 levels week 44 0.7 (0.4 to 2.3) SLIT versus 0.5 (0.2 to 0.7) placebo (NS). Increase between baseline and week 44 in SLIT.
Kim, 2010; USA	Specific IgE IgG4 (peanut specific)	Peanut-specific IgE and IgG4 levels were measured with the Phadia AB ImmunoCAP 100 instrument.	Serum was obtained at baseline, 4 months, 8 months, and the day of DBPCFC (after 12 months of SLIT).	After 12 months, peanut SLIT results in an increase in specific IgE levels over 4 months followed by a decrease over the subsequent 8 months. IgG4 levels in the active group increased significantly during 12 months compared to the placebo group.

First author, year,	Immunoglobulin measured	Method of	Time parameters	Findings
country		measurement		
Lacono, 2013; Italy	Specific IgE (specific to HE)	Not specified	At baseline, after 6 months.	In SOTI group egg-specific IgE decreased significantly compared to controls at 6 months (p=0.007).
Longo, 2008; Italy	Specific IgE (CM specific)	Specific IgE levels were measured by using the Phadia CAP System FEIA.	Specific IgE levels in serum samples were measured at the time of enrolment, and after 6 and 12 months.	Specific IgE measured at 6 and 12 months showed a significant decrease after SOTI in 15 of 30 subjects. (cut-off point of 100 kUA/L)
Martorell, 2011; Spain	Specific IgE (CM specific)	Specific IgE levels were measured by using the Phadia CAP System FEIA.	At baseline and after 12 months	Specific IgEs decreased significantly in active group compared to controls after 12 months (p<0.0001).
Meglio, 2013; Italy	Specific IgE (specific to HE)	Specific IgEs and IgG4s to HE proteins were determined with Realtest (Reverse Enzyme Alergo Sorbent Test – Reast) (Lofarma) and an allergen microarray assay (Immuno Solid- phase Allergen Chip ISAC).	At baseline and after 6 months (pre and post desensitisation period).	The differences between specific IgEs before and after the treatment were significant only in the active group (p=0.01) (ISAC method). No comparisons between groups.
Morisset, 2007; France	Specific IgE (specific to CM and HE)	Specific IgE levels were measured by using the CAP system FEIA.	Specific IgE levels were assessed at: baseline and 6 months.	Specific IgEs decreased in both groups. However, the decrease in IgE was greater in the "recovery" sub-group: $3.07 \text{ vs. } 1.6 \text{ kU/l} (p < 0.1)$ and $8.21 \text{ vs. } 6.7 \text{ kU/l}$ in the "failure" sub-group (p ns).

First author, year,	Immunoglobulin measured	Method of	Time parameters	Findings
country		measurement		
Pajno, 2010; Italy	Specific IgE IgG4 (CM specific)	Specific IgE and IgG4 were assayed using the ImmunoCAP system.	Blood samples were collected before randomization, when the dose of 8mL (volume of whole milk. Soy milk was the control treatment.) was reached (week13), and at the end of the study (18 weeks).	No significant difference in specific IgE levels between the active and control groups. At week 18 the levels of IgG4 in the active group was significantly higher than in the control group.
Patriarca, 1998; Italy	Total IgE Specific IgE (specific to CM, HE, fish and apple)	Total IgE was measured by employing PRIST (paper radioimmunosorbent test). Specific IgE was assessed by using a radio- immunoenzymatic assay. (RAST)	Both control and treated subjects were examined after a 6 month period (the desensitization protocol took 4 months on average). The treated subjects were then controlled periodically over a 3 to 6 year follow- up period.	No change was observed in IgE.
Skripak, 2008; USA	Total IgE Specific IgE IgG IgG4 (specific to CM)	Total IgE and the levels of IgE, IgG, and IgG4 antibodies were measured by using the Phadia CAP-system FEIA.	Blood samples were collected before immunotherapy, when the maintenance dose was reached, and after completion of immunotherapy.	Total serum IgE levels did not change, on average. Milk-specific IgE levels did not change significantly in either group. Although there was no significant change in CM IgG4 levels in the placebo group, there was a median increase from baseline of 767% in the active group ( $P = 0.002$ ). CM-specific IgG antibody levels increased in parallel with the IgG4 antibody levels.

First author, year,	Immunoglobulin measured	Method of	Time parameters	Findings
country		measurement		
Staden, 2007; Germany	Total IgE Specific IgE (specific to CM and HE)	Total IgE and specific IgE were measured using the Phadia CAP- system FEIA.	Blood sample was drawn prior to start of the intervention, prior to re- challenges or at final examination.	With respect to total IgE there was no significant alteration in values for either SOTI or elimination group (data not shown). Specific IgE decreased significantly over time in children who developed their natural tolerance under elimination diet as expected ( $P < 0.05$ ). Under intervention with SOTI, children in the responder group and partial responder groups showed a similar response ( $P < 0.001$ ). There was no significant change in specific IgE in children who had to stop SOTI and the ones who were non-responders under elimination diet. Children in the SOTI group who were responders had lower specific IgE levels than the non-responders at the beginning of the study ( $P < 0.05$ ).
Varshney, 2011; USA	Specific IgE IgG IgG4 (peanut specific)	Peanut-specific IgE, IgG, and IgG4 levels were measured by using the ImmunoCAP 100 instrument (Phadia AB).	Serum immunoglobulin levels were analysed at regular intervals: baseline, 2 months, 6 months, 9 months and at OFC (week 48).	In the active group, median peanut- specific IgE increased nearly 3-fold by 2 months and was not significantly different from baseline at OFC; the placebo group showed no changes. The active group had significant increases in peanut-specific IgG at all time points. Peanut-specific IgG4 showed a significant increase from baseline at all time points with peanut OIT and did not change with the placebo group.

Iran	Specific IgE (CM specific)	measured qualitatively (an ELISA was performed).	measured during: pre- observational period & post-observational period (for the control group) and pre-desensitization & post-desensitization (for the case group). Total IgE was measured before the study but was not rechecked afterwards.	0.004); specific IgE reduced after desensitisation (P = 0.001).
Patriarca, 2003; Italy	Total IgE Specific IgE IgG4 (specific to CM, HE, fish, orange, peanut, corn, peach, apple, lettuce and beans)	Total and specific IgE and specific IgG4 in the serum were detected with an immuno-enzymatic assay (UniCAP was used to detect IgE and CAP FEIA was used to detect IgG4).	Specific IgE and IgG4 in the serum were measured at: baseline and after 6, 12 and 18 months.	During the oral desensitization, there was a significant decrease in specific IgE after 6 (P < 0.01), 12 (P < 0.01) and 18 months (P < 0.01), and a significant increase in specific IgG4 after 6 (P < 0.01), 12 (P < 0.01) and 18 months (P < 0.01).
Patriarca, 2007; Italy	Total IgE Specific IgE IgG4	UniCAP [Pharmacia] was used to detect IgE and CAP FEIA [Pharmacia] was used to detect IgG4.	IgE and IgG4 levels were monitored at: baseline and 6, 12, & 18 months after starting the protocol in all patients who completed the treatment successfully.	During the oral desensitizing treatment, a significant decrease was observed in specific IgE after 6 (P < 0.001), 12 (p = $0.004$ ), and 18 (P = $0.002$ ) months and a significant increase in specific IgG4 after 6 (P < $0.001$ ), 12 (P < $0.001$ ), and 18 (P < $0.001$ ), and 18 (P < $0.001$ ) months.

Enrique, 2005; Spain Enrique, 2008^	IL-4, IL-5, IL-10, TGF-β, and IFN-γ.	ELISA	Blood samples taken before treatment for in vitro studies. Blood samples were again drawn for in vitro studies 8-12 weeks later (at time of final DBPCFC).	An increase in IL-10 levels after SLIT was found only in the active group, rising from 1.62 pg/mL to 2.24 pg/mL (P < 0.05). No differences were observed between the placebo and active groups. Unable to obtain results for the other cytokines because of the low sensitivity of the tests used.
Kim, 2010; USA	IL-5, IL-10, IL-13, and IFN-γ.	ELISA	Cytokine levels measured at baseline and after 12 months of peanut SLIT or placebo.	After 12 months, peanut SLIT results in a decrease in IL-5 secretion. After 12 months, IL- 13 levels in the active treatment group decreased from a median of 147.1 pg/mL at baseline to 62.1pg/mL. However, this level was not significant compared with that in the placebo group (P= 0.06), which also decreased from a median baseline of 369.6 pg/mL to 149.55 pg/mL after 12 months. No differences between the 2 groups were found in IL-10 or IFN-γ levels at baseline or at 12

				months (data not shown).
Meglio, 2013; Italy	IL-4, IL-5, IL-6, Il-10, IL- 13, IFN-γ, TNF-α, TGF-β1 and TGF-β2	ELISA	Pre and post desensitisation period	Only a significant increase of IL- 5 in the active group was observed (pre: mean, $19.00 \pm 9.4$ pg/ml; range, $5.00-32.00$ ; post $28.13 \pm 14.7$ pg/ml; range, 12.00-56.00 - p=0.03). All other differences were not significant
Varshney, 2011; USA	IL-5, IL-10, IL-13, IFN-γ, and TGF-β.	ELISA	Cytokine analysis occurred at: baseline, 9months, and the time of oral food challenge (OFC performed after approximately 1 year of OIT).	IL-5 and IL-13 decreased in peanut OIT subjects. Also, there was a transient increase in TGF- $\beta$ in the active group at 9 months but levels returned to the baseline at OFC. No change in IL-5, IL-13, or TGF- $\beta$ in placebo group. No significant change in IL-10 or IFN- $\gamma$ in either the active or placebo group.
