Material and Methods

Flock location and management

The study was performed in one flock, located in Beskydy Mountain, Moravian-Silesian region at the altitude 450 – 890 m a.s.l. (above sea level). The local annual rainfall was 833 mm and the average annual temperature was 7.0°C in the evaluated year. The sheep were naturally grazed on the permanent pasture under traditional Carpathian management system, lying in free motion on pastures, selective grazing montane region of Beskydy Mountains, and no concentrates supply. Ewes had access to hay (ad libitum) as additional supplement to compensate potential lack of nutrition obtained from forage pasture. Pastures can be characterized as mesic Arrhenatherum grassland (dominant species Festuca rubra, Festuca pratensis, Poa pratensis) or Cynosurus pasture (dominant species Cynosurus cristatus, Festuca pratensis, Trisetum flavescens). The soil type was classified as Cambisol in the pasture areas. The stocking rate was 0.76 livestock units per hectare. The lambing occurred from the beginning of March to mid. April on pastures. After lambing all lambs were identified to their mothers, weighted and tagged. The lambs were kept together with their
mothers up to fifth month of age (end of July), when the ram lambs were separated from the flock. Ewe lambs were kept with their mothers up to mating period.

**FAs profile estimation**

The gravimetric method was performed for milk fat extraction (ČSN EN ISO 1211 (570534)). The milk fat extract (60 mg) was obtained using a water-based-solution of ammonia, ethanol, diethyl ether and petroleum ether. FA methyl esters were prepared by the potassium hydroxide catalysed methylation and extracted into hexane. Gas chromatography (GC, FID) of FA methyl esters was performed using the Master GC (DANI Instruments S.p.A.; Italy) (split regime, FID detector) on a column with polyethylene glycol stationary phase (FameWax – 30 m × 0.32 mm × 0.25 μm). Helium was used as the carrier gas at a flow rate of 5 ml × min⁻¹. The temperature programme used for GC was as follows: 50 °C (2 min), after which the temperature was increased to 230 °C at 10 °C × min (8 min), the temperature of the detector being 220 °C.

**Statistical evaluation**

The following statistical model was used for all FAs or FA groups evaluation:

\[ Y_{ijklm} = \text{DAY}_i + \text{AGE}_j + \text{DIM}_k \text{ (DAY)} + a_{l} + e_{ijklm} \]

Where:

\[ Y_{ijklm} = \text{measured or assessed trait}; \]

\[ \text{DAY}_i = \text{fixed effect of control day of milk collection (i = 1}\text{st day of milk collection, n = 38}; i = 2\text{nd day of milk collection, n = 35}; i = 3\text{rd day of milk collection, n = 35}; i = 4\text{th day of milk collection, n = 32}); \]
AGE\_j = \text{fixed effect of ewe age category (j = 1 year old ewes, n = 14; j = 2 years old ewes, n = 20; j = 3 years old ewes, n = 44; j = 4 years old ewes, n = 33; j = 5 years and older ewes, n = 29)};
\[\text{DIM}_{k} (\text{DAY}) = \text{nested effect of days in milk within particular control days of milk collection};\]
an\_i = \text{animal (random effect)};
\[\text{e}_{ijklm} = \text{residual error}.\]
The Tukey-Kramer method was used for evaluation of differences between least square means. Significance level P < 0.05 was used to evaluate the differences among groups.
