

## Internet Appendix for “The Puzzle of Frequent and Large Issues of Debt and Equity”

January 23, 2020

### List of Internet Appendix Tables

- IA-1: List of Frequent Issuers in the Fiscal Years from 2005–2007
- IA-2: Sample Distribution by Issue Recency, 1974–2017
- IA-3: Sample Distribution of Non-Microcaps, 1974–2017
- IA-4: Average Firm Characteristics sorted by Large Issues, 1974–2017
- IA-5: Calendar-Time Factor Regressions, Equity Issues, Additional Results
- IA-6: Calendar-Time Factor Regressions, Debt Issues, Additional Results
- IA-7: Calendar-Time Factor Regression *Equal-Weighted* Results, Purged Q-Factors
- IA-8: Calendar-Time Factor Regressions, Equity and Debt Issues Combined, Additional Results
- IA-9: Calendar-Time Factor Regression Results, Subperiod Analysis
- IA-10: Calendar-Time Regressions of *Value-Weighted* Returns, Additional Subperiod Analysis
- IA-11: Calendar-Time Regressions of *Equal-Weighted* Returns, Additional Subperiod Analysis
- IA-12: Fama-MacBeth Regressions of Stock Returns, *Equally Weighted* OLS Results, Excluding Microcaps (528 Months, 1975–2018)
- IA-13: Fama-MacBeth Regressions of Stock Returns, Alternative Control Variables (528 Months, 1975–2018)
- IA-14: Fama-MacBeth Regressions of Stock Returns, Additional Results
- IA-15: Fama-MacBeth Regressions of Earnings Announcement Returns, *Equally Weighted* OLS Results, Excluding Microcaps
- IA-16: Fama-MacBeth Regressions of Earnings Announcement Returns, Alternative Control Variables
- IA-17: Fama-MacBeth Regressions of Earnings Announcement Returns, Additional Results

In Table IA-1 of this Internet Appendix, we list the companies that conducted an equity issue in each of the fiscal years 2005–2007 (three issues) in Panel A, those that conducted a debt issue in each of these fiscal years (three issues) in Panel B, and the companies that conducted six issues (both debt and equity issues in each of the three years) in Panel C.

Inspection of the table shows that the issuers share the characteristics reported in Tables 2 and 3 of our paper: equity issuers tend to be small, unprofitable firms; and both debt and equity issuers tend to have heavy investment. Inspection of the table also discloses heavy industry clustering: many of the equity issuers are biotech firms (SIC code starting with 283 or 8731) or biopharma firms (we call both biotech throughout the paper), and many of the debt issuers are oil & gas producers. Other years show clustering in other industries: in much of the 1980s and 1990s, software and hardware firms were heavily represented among equity issuers.

The  $\text{Return}_{t+1}$  numbers are strongly negative for most of the stocks in this cohort of issuing firms listed, reflecting the 2008 bear market. For firms with a Dec. 31, 2007 fiscal year-end, the  $\text{Return}_{t+1}$  period is May 2008–Apr 2009. Note, however, that the vast majority of both debt and equity issuers had negative market-adjusted returns, as well as negative values for  $\text{Return}_{t+1, t+3}$ .

In this Internet Appendix, Table IA-2 reports the sample distribution by issue recency. Panels A-C of Table IA-3 are similar to Panels A-C of Table 2 in the paper but reports the distribution of only non-microcaps in our sample, and shows that many frequent issuers of debt or equity are not microcaps. Panels D and E of Table 2 report the sample distribution by issue recency after excluding microcaps for all issues and large issues, respectively. Table IA-4 reports average firm characteristics sorted by large security issues. Relative to security issuers in Table 3 of the paper, firms with larger issues in Table IA-4 are generally slightly smaller and less

profitable, and have higher asset growth. Other than that, the patterns in Table IA-4 are similar to the patterns in Table 3.

Tables 4-8 in the paper always report the q-factor model calendar-time regression results of *value-weighted* (VW) portfolios, and sometimes report the Fama-French 5-factor model results or *equal-weighted* (EW) results. Correspondingly, in the Internet Appendix, Tables IA-5 through IA-9 complement Tables 4-8 by reporting the market model and 3-factor model results, and the 5-factor model results if they are not reported in the paper. Tables IA-5 through IA-9 also report the EW results, if they are not reported in the paper. Table IA-5 reports the results for equity issues, Table IA-6 reports the results for debt issues, Table IA-7 reports the EW results using purged q-factors, Table IA-8 reports the results for both debt and equity issues, and Table IA-9 shows the results for two subperiods.

Table 4 and Table IA-5 show that the difference between the intercepts for the VW portfolios of non-issuers and frequent equity issuers ( $\geq 2$ ) is 0.77% in the market model, but it shrinks to 0.72% in the 3-factor model, and to 0.51% in the 5-factor model and 0.47% in the q-factor model. Thus, size, book-to-market, profitability, and investment patterns are able to explain only a modest portion of the spread in intercepts between non-issuers and frequent equity issuers. Even after controlling for these factors, frequent equity issuers reliably underperform non-issuers.

Tables 4 and IA-5 shows that, relative to the market model, the multifactor models shrink the differences in abnormal returns across the portfolios sorted by equity issue frequency. In contrast, as can be seen from Tables 5 and IA-6, the market model slightly outperforms the three multifactor models in explaining stock returns across the portfolios sorted by debt issue frequency. The spread between the intercepts for the zero debt issue portfolio and the frequent

debt issue ( $\geq 2$ ) portfolio is 0.20% in the market model, 0.28% in the 3-factor model, 0.27% in the 5-factor model, and 0.24% in the q-factor model.

Table 1 of Fu and Huang (2016) reports calendar-time regression results with VW abnormal returns following seasoned equity offerings of -16.20% per year during 1980–2002 and -0.36% per year during 2003–2012. Our Tables IA-10 and IA-11 report the calendar-time regression results for 2003–2012 and several other subperiods.

Tables IA-12, IA-13, and IA-14 add to Table 9 in the paper. Table 9 reports the results for the Fama-MacBeth (FM) regressions of monthly portfolio returns using ordinary least squares (OLS) and weighted least squares (WLS). Although microcaps are unlikely to have material effects on the WLS results, a few firms with the largest market caps can have large effects on the WLS results. Table IA-12 reports the FM OLS regression results of monthly portfolio returns after excluding microcaps from the sample, effectively preventing microcaps or a few firms with the largest market caps from having too much influences. Tables IA-13 reports the FM results of monthly portfolio returns using alternative control variables. Table IA-14 reports FM regression results of monthly portfolio returns for large issues, issue recency, and the subperiods.

Tables IA-15, IA-16, and IA-17 report the FM regression results of earnings announcement returns (EARs), adding to Table 10 in the paper. Table IA-15 reports the results of the FM regressions of EARs using OLS after excluding microcaps from the sample. Tables IA-16 reports FM EAR results using alternative control variables. Table IA-17 reports FM EAR results for large issues, issue recency, and the subperiods.

**TABLE IA-1: List of Frequent Issuers in the Fiscal Years from 2005–2007**

Table IA-1 shows the lists of firms with frequent issues in the fiscal years from 2005–2007 as well as their characteristics during or at the end of fiscal year 2007 and subsequent stock returns. Panel A shows the list of 117 firms with three equity issues. Panel B shows the list of 66 firms with three debt issues. Panel C shows the list of 3 firms with three equity issues and three debt issues. SIC code is the four-digit historical SIC code. Market cap is expressed in \$millions at the end of fiscal year 2007 (not adjusted for inflation). Asset Growth is the growth rate of assets in 2007. OIBD÷Assets is OIBD in 2007 scaled by the book value of assets at the end of 2006, and Qtr. ROE is net income in the 4<sup>th</sup> quarter of 2007 scaled by the book value of equity at the end of the 3<sup>rd</sup> quarter. The three-year and one-year raw and market adjusted stock returns are measured from the 5<sup>th</sup> month of fiscal year 2008. See Appendix A and Table 1 for detailed variable definitions.

Panel A. Firms with Three Equity Issues from 2005–2007

**TABLE IA-2****Sample Distribution by Issue Recency, 1974–2017**

Table IA-2 reports the sample distribution by issue recency. A firm is defined to have an equity issue (a debt issue) in a year if  $\Delta\text{Equity}$  ( $\Delta\text{Debt}$ ) in the year is at least 5% of the book value of beginning-of-year assets and at least 3% of the market value of beginning-of-year equity. A firm is defined to have a large equity issue (a large debt issue) in a year if  $\Delta\text{Equity}$  ( $\Delta\text{Debt}$ ) in the year is at least 10% of the book value of beginning-of-year assets and at least 3% of the market value of beginning-of-year equity. See Appendix A for the definitions of  $\Delta\text{Equity}$  and  $\Delta\text{Debt}$ . Equity issues of (0,0,1), for example, denotes that the firm conducted no equity issue in t and t-1 but did an equity issue in t-2.

**TABLE IA-3: Sample Distribution of Non-Microcaps, 1974–2017**

Table IA-3 reports the distribution of the sample that excludes microcaps. A firm is defined as a microcap if its market cap at the end of fiscal year  $t$  is less than or equal to the 20<sup>th</sup> percentile of the market caps of all NYSE-listed stocks on the same date. A firm is defined to have an equity issue (a debt issue) in a year if  $\Delta$ Equity ( $\Delta$ Debt) in the year is at least 5% of the book value of beginning-of-year assets and at least 3% of the market value of beginning-of-year equity. A firm is defined to have a large equity or debt issue using the same definitions except with 10% replacing 5%. No. of equity (debt) issues equals the number of fiscal years with equity (debt) issues in fiscal years  $t-2$ ,  $t-1$ , and  $t$ . No. of issues equals the total number of equity or debt issues in fiscal years  $t-2$ ,  $t-1$ , and  $t$ . No. of large equity (or large debt) issues equals the number of fiscal years with large equity (debt) issues in fiscal years  $t-2$ ,  $t-1$ , and  $t$ . No. of large issues equals the total number of large equity or large debt issues in fiscal years  $t-2$ ,  $t-1$ , and  $t$ . See Appendix A for the definitions of  $\Delta$ Equity and  $\Delta$ Debt. In Panels D and E, (0,0,1) for equity issues, for example, denotes that the firm conducted no equity issue in  $t$  and  $t-1$  but did an equity issue in  $t-2$ .

Panel A: Sample Distribution by Number of Issues and Number of Large Issues, Independently

All issues			Large issues

**TABLE IA-5: Calendar-Time Factor Regressions, Equity Issues, Additional Results**

See Appendices A and B and Table 1 for the definitions of variables, the q-factor model, and the Fama-French 5-factor model. The market model is based on the equation  $R_{it} - R_{Ft} = a_i + b_i(R_{Mt} - R_{Ft}) + e_{it}$ , and the Fama-French 3-factor model is based on the equation  $R_{it} - R_{Ft} = a_i + b_i(R_{Mt} - R_{Ft}) + s_iSMB_t + h_iHML_t + e_{it}$ , where subscript i denotes portfolio i, and subscript t denotes month t. See Fama and French (2015 and 2016a) for details. The factor return data are from Kenneth French’s website. The dependent variable is the portfolio monthly value-weighted (VW) or equal-weighted (EW) percentage excess return. If there are less than 10 stocks in the portfolio in a month, the corresponding observation is dropped. *T*-statistics using a Newey-West correction with 3 lags are in parentheses, with \*, \*\*, and \*\*\* signifying statistical significance at the 10%, 5%, and 1% significance levels.

**TABLE IA-6: Calendar-Time Factor Regressions, Debt Issues, Additional Results**

See Appendices A and B, Table 1, and Table IA-5 for variable and factor model descriptions. The dependent variable is the portfolio monthly value-weighted (VW) or equal-weighted (EW) percentage excess return. If there are less than 10 stocks in the portfolio in a month, the corresponding observation is dropped. *T*-statistics using a Newey-West correction with 3 lags are in parentheses, with \*, \*\*, and \*\*\* signifying statistical significance at the 10%, 5%, and 1% significance levels.

**TABLE IA-7: Calendar-Time Factor Regression *Equal-Weighted* Results, Purged Q-Factors**

This table reports the equal-weighted (EW) results using purged q-factors. The dependent variable is the monthly EW percentage portfolio return minus the risk free rate. If there are less than 10 stocks in the portfolio in a month, the corresponding observation is dropped. To construct the purged q-factor series, we start with replicating Hou, Xue, and Zhang's (2015, 2018a, and 2018b) q-factor series. From 1975–2018, the correlation between our replicated and the original size factor monthly series provided by Lu Zhang is 0.996, the correlation between the replicated and original ROE factor monthly series is 0.992, and the correlation between the replicated and original asset growth factor monthly series is 0.981. The size, asset growth, and ROE factors used in columns (1)-(3) are computed after purging stocks of firms with one or more equity issues in years  $t-2$  to  $t$ , and those in (4)-(6) are computed after purging stocks of firms with one or more debt issues in years  $t-2$  to  $t$ . The market factor is not purged. To facilitate comparison, Panel A reports non-purged results. See Appendices A and B and Table 1 for variable and q-factor model descriptions. *T*-statistics using a Newey-West correction with 3 lags are in parentheses, with \*, \*\*, and \*\*\* signifying statistical significance at the 10%, 5%, and 1% significance levels.

	(1)	(2)	(3)	(4)	(5)	(6)
	No. of equity issues=0	No. of equity issues $\geq$ 2	Equity issues (1,1,0) or (1,1,1)	No. of debt issues=0	No. of debt issues $\geq$ 2	Debt issues (1,1,0) or (1,1,1)

**TABLE IA-8: Calendar-Time Factor Regressions, Equity and Debt Issues Combined, Additional Results**

See Appendices A and B, Table 1, and Table IA-5 for variable and factor model descriptions. The number of issues represents the number of the last three fiscal years in which a debt or equity issue occurred, with a maximum of 6 potential issues. The dependent variable is the monthly percentage value-weighted (VW) or equal-weighted (EW) portfolio return minus the risk free rate. If there are less than 10 stocks in the portfolio in a month, the corresponding observation is dropped. *T*-statistics using a Newey-West correction with 3 lags are in parentheses, with \*, \*\*, and \*\*\* signifying statistical significance at the 10%, 5%, and 1% significance levels.

**TABLE IA-9: Calendar-Time Factor Regression Results, Subperiod Analysis**

See Appendices A and B, Table 1, and Table IA-5 for variable and factor model descriptions. The dependent variable is the monthly percentage value-weighted (VW) or equal-weighted (EW) portfolio return minus the risk free rate. If there are less than 10 stocks in the portfolio in a month, the corresponding observation is dropped. *T*-statistics using a Newey-West correction with 3 lags are in parentheses, with \*, \*\*, and \*\*\* signifying statistical significance at the 10%, 5%, and 1% significance levels.

## Panel A. VW Results

	(1) 1975–1996 (Number of months = 264)					(2) 1997–2018 (Number of months = 264)				
	No. of equity issues $\geq 2$	No. of debt issues $\geq 2$	Equity issues (1,1,0) or (1,1,1)	Debt issues (1,1,0) or (1,1,1)	No. of large issues $\geq 3$	No. of equity issues $\geq 2$	No. of debt issues $\geq 2$	Equity issues (1,1,0) or (1,1,1)	Debt issues (1,1,0) or (1,1,1)	No. of large issues $\geq 3$

**TABLE IA-11: Calendar-Time Regressions of *Equal-Weighted Returns*, Additional Subperiod Analysis**

This table reports the equal-weighted (EW) results of calendar-time regressions for different periods to compare with those of Fu and Huang (*Management Science* 2016). See Appendices A and B, Table 1, and Table IA-5 for variable definitions. *T*-statistics using a Newey-West correction with 3 lags are in parentheses, with \*, \*\*, and \*\*\* signifying statistical significance at the 10%, 5%, and 1% significance levels.

**TABLE IA-12: Fama-MacBeth Regressions of Stock Returns, Equally Weighted OLS Results, Excluding Microcaps (528 Months, 1975–2018)**

Cross-sectional regressions are estimated each month. The dependent variable is the monthly return (in percent) on a firm's stock. A firm is defined as a microcap if its market cap at the end of fiscal year  $t$  is less than or equal to the 20<sup>th</sup> percentile of the market caps of all NYSE-listed stocks on the same date. The top and bottom 1% values of  $\text{Ln}(\text{Market Cap})_t$ ,  $\text{Asset Growth}_t$ , and  $\text{Qtr. ROE}_{t+}$  are winsorized for each regression sample.  $\text{Qtr. ROE}_{t+}$  equals the most recent quarterly earnings announced prior to the month of the regression divided by beginning-of-quarter book value of equity. To avoid stale earnings, it is also required that the fiscal quarter that corresponds to the announced earnings ends no more than six months prior to the month of the regression. The other control variables have values from fiscal year  $t$  ending at least four months prior to the month of the regression. This table reports the time-series averages of the monthly coefficients and the corresponding Newey-West  $t$ -statistics that correct the for first, second, and third order autocorrelations. See Appendix A and Tables 1 and 9 for variable definitions.

**TABLE IA-13: Fama-MacBeth Regressions of Stock Returns, Alternative Control Variables (528 Months, 1975–2018)**

Cross-sectional regressions are estimated each month. The dependent variable is the monthly return (in percent) on a firm's stock. The weighted least squares (WLS) results use the market value of equity (the number of shares outstanding  $\times$  price per share from CRSP) as the weight. When there are multiple share classes, the market values of all classes of shares are added. The top and bottom 1% values of  $\text{Ln}(\text{Market Cap})_t$ ,  $\text{Asset Growth}_t$ ,  $\text{Market-to-Book}_t$ , and  $\text{OIBD} \div \text{Assets}_t$  are winsorized for each regression sample. The control variables have values from fiscal year  $t$  ending at least four months before the month of the regression. This table reports the time-series averages of the monthly coefficients and the corresponding Newey-West  $t$ -statistics that correct for first, second, and third order autocorrelations. See Appendix A, Tables 1 and 9, and Table IA-12 for the definitions of microcaps and other variables.

**TABLE IA-14: Fama-MacBeth Regressions of Stock Returns, Additional Results**

Cross-sectional regressions are estimated each month. The dependent variable is the monthly percentage return on a firm's stock. The weighted least squares (WLS) results use the market value of equity (the number of shares outstanding  $\times$  price per share from CRSP) as the weight. When there are multiple share classes, the market values of all classes of shares are added. The top and bottom 1% values of  $\text{Ln}(\text{Market Cap})_t$ ,  $\text{Asset Growth}_t$ , and  $\text{Qtr. ROE}_{t+}$  are winsorized for each regression sample. The control variables have values from fiscal year  $t$  ending at least four months before the month of the regression. This table reports the time-series averages of the monthly coefficients and the corresponding Newey-West  $t$ -statistics that correct for first, second, and third order autocorrelations in parentheses, with \*, \*\*, and \*\*\* signifying statistical significance at the 10%, 5%, and 1% significance levels. See Appendix A, Tables 1 and 9, and Table IA-12 for the definitions of microcaps and other variables.

**TABLE IA-15: Fama-MacBeth Regressions of Earnings Announcement Returns, *Equally Weighted OLS Results, Excluding Microcaps***

The dependent variable is the average three-day buy-and-hold return (in percent) from one day before to one day after the quarterly earnings announcement date (Compustat item RDQ) for all earnings announcements made from 123 to 488 calendar days after the end of fiscal year  $t$ . We estimate cross-sectional regressions for returns in each of the calendar years from 1975–2018, using observations with the fiscal year end date that falls into the prior calendar year. A firm is defined as a microcap if its market cap at the end of fiscal year  $t$  is less than or equal to the 20<sup>th</sup> percentile of the market caps of all NYSE-listed stocks on the same date. The top and bottom 1% values of  $\text{Ln}(\text{Market Cap})_t$ ,  $\text{Asset Growth}_t$ , and  $\text{Qtr. ROE}_t$  are winsorized for each regression sample.  $\text{Qtr. ROE}_t$  equals earnings in the 4<sup>th</sup> quarter of fiscal year  $t$  divided by beginning-of-quarter book value of equity. This table reports the average of the annual coefficients and the corresponding Newey-West t-statistics that correct for first-order autocorrelation. See Appendix A and Tables 1 and 10 for variable definitions.

**TABLE IA-16: Fama-MacBeth Regressions of Earnings Announcement Returns, Alternative Control Variables**

The dependent variable is the average three-day buy-and-hold return (in percent) from one day before to one day after the quarterly earnings announcement date (Compustat item RDQ) for all earnings announcements made from 123 to 488 calendar days after the end of fiscal year  $t$ . We estimate cross-sectional regressions for each of the calendar years from 1975–2018, using observations with the fiscal year end date that falls into the prior calendar year. The weighted least squares (WLS) results use the market value of equity at the end of fiscal year  $t$  from Compustat as the weight, adjusting for inflation within the year for firms with different fiscal year ends. The top and bottom 1% values of  $\text{Ln}(\text{Market Cap})_t$ ,  $\text{Asset Growth}_t$ ,  $\text{Market-to-Book}_t$ , and  $\text{OIBD} \div \text{Assets}_t$  are winsorized. This table reports the average of the annual coefficients and the corresponding Newey-West  $t$ -statistics that correct for first-order autocorrelation. See Appendix A, Tables 1 and 10, and Table IA-15 for the definitions of microcaps and other variables.

**TABLE IA-17: Fama-MacBeth Regressions of Earnings Announcement Returns, Additional Results**

The dependent variable is the average three-day buy-and-hold return (in percent) from one day before to one day after the quarterly earnings announcement date (Compustat item RDQ) for all earnings announcements made from 123 to 488 calendar days after the end of fiscal year  $t$ . We estimate cross-sectional regressions for each of the calendar years from 1975–2018, using observations with the fiscal year end date that falls into the prior calendar year. The weighted least squares (WLS) results use the market value of equity at the end of fiscal year  $t$  from Compustat as the weight, adjusting for inflation within the year for firms with different fiscal year ends. The top and bottom 1% values of  $\text{Ln}(\text{Market Cap})_t$ ,  $\text{Asset Growth}_t$ ,  $\text{Qtr. ROE}_t$ ,  $\text{Market-to-Book}_t$ , and  $\text{OIBD} \div \text{Assets}_t$  are winsorized.  $\text{Qtr. ROE}_t$  equals earnings in the 4<sup>th</sup> quarter of fiscal year  $t$  divided by beginning-of-quarter book value of equity. This table reports the average of the annual coefficients and the corresponding Newey-West  $t$ -statistics that correct for first-order autocorrelation. See Appendix A, Tables 1 and 10, and Table IA-15 for the definitions of microcaps and other variables.
