ABSTRACT. The Supplementary Material contains ten Figures and four Tables providing additional background and data supporting the main text.

Supplementary Fig. 1. Spatial snow distribution multiplier D_{snow} (Eq. 3 of main text). D_{snow} is only relevant for the glacierized area (within blue outline, corresponding to 2013) but is shown over a larger domain for illustration. Dark areas (low values of D_{snow}) correspond to regions with high surface slopes (mostly rock faces) with limited snow deposition that are consequently ice-free. The variability in D_{snow} over most of Claridenfirn's surface is rather small, except for wind-shaded areas along the northern boundary (above-average snow deposition according to D_{snow}), and in the region of the ice cliff due to steep terrain (below-average snow deposition).

Supplementary Fig. 2. Evolution of the ice cliff and the situation in the depositional zone of ice avalanches based on topographic maps of the Federal Office of Topography. Until the 1970s, a fully connected regenerated glacier was present below the ice cliff. It likely held a part of the ice avalanche deposits, although bigger avalanches were able to reach the valley floor. This lowermost part of Claridenfirn retreated and finally disconnected, increasing potential losses due to ice avalanches.

Supplementary Fig. 3. Evolution of the ice cliff and the situation in the depositional zone of ice avalanches based on selected aerial photographs of the Federal Office of Topography. Cases with observed avalanche deposits in the valley floor are indicated. Out of the totally thirteen available aerial images, four (1956, 1979, 2007, 2010) indicate avalanche deposits outside the glacier's perimeter, i.e. on the valley floor at about 2000 m a.s.l.. All images show small local ice avalanche activity.

Ice cliff and underlying glacier tongue (1935)

Ice cliff and underlying glacier tongue (1935)

North-eastern part of ice cliff (2011)

Central part of ice cliff (2011)

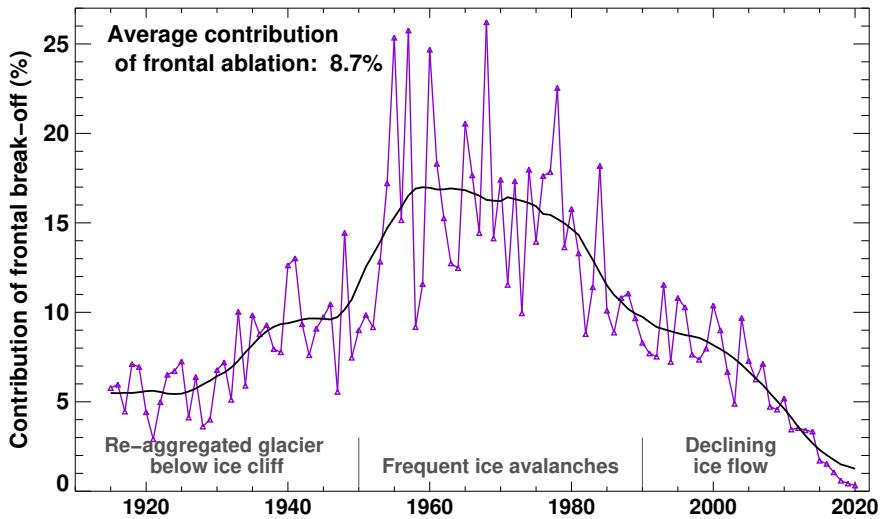

South-western part of ice cliff (2011)

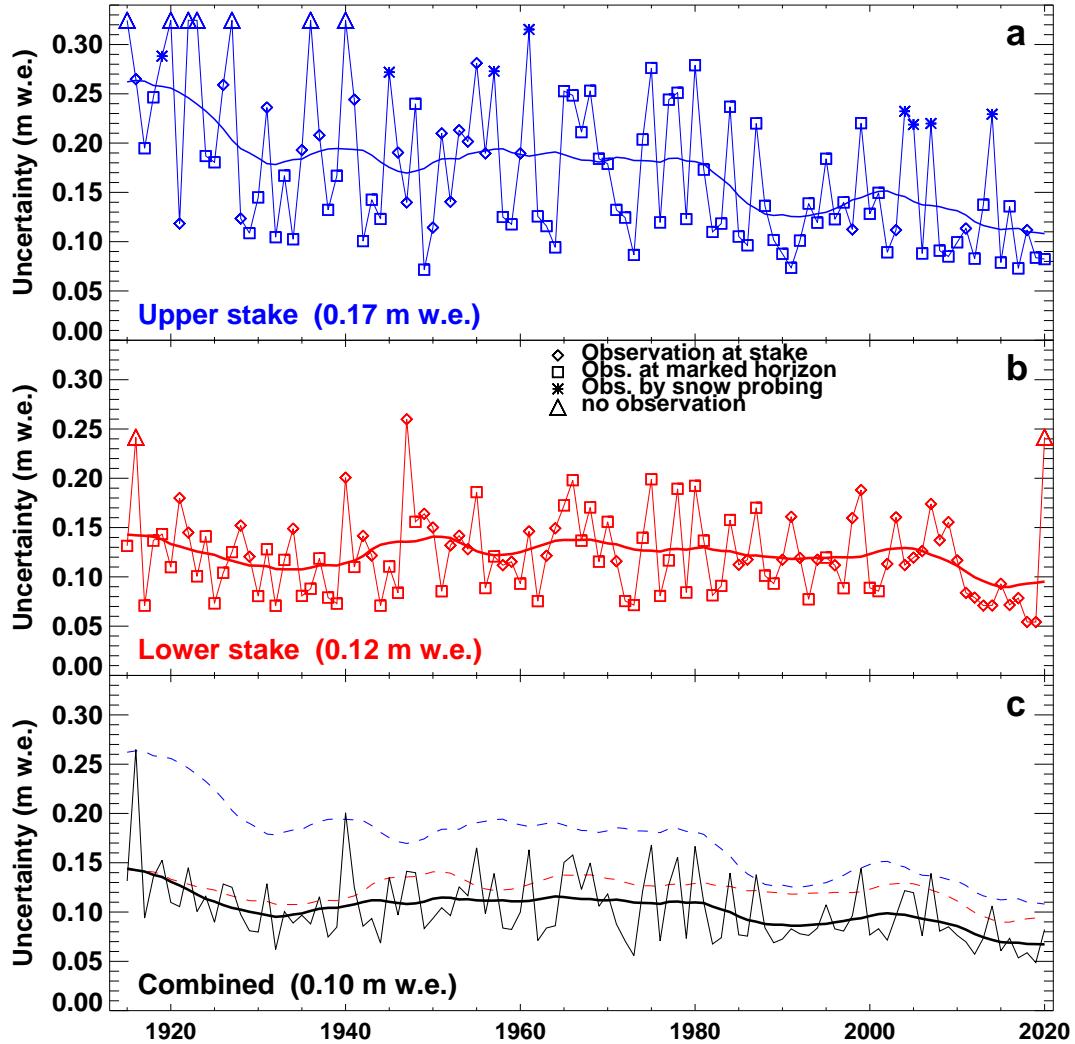

Overview of ice cliff (2016)

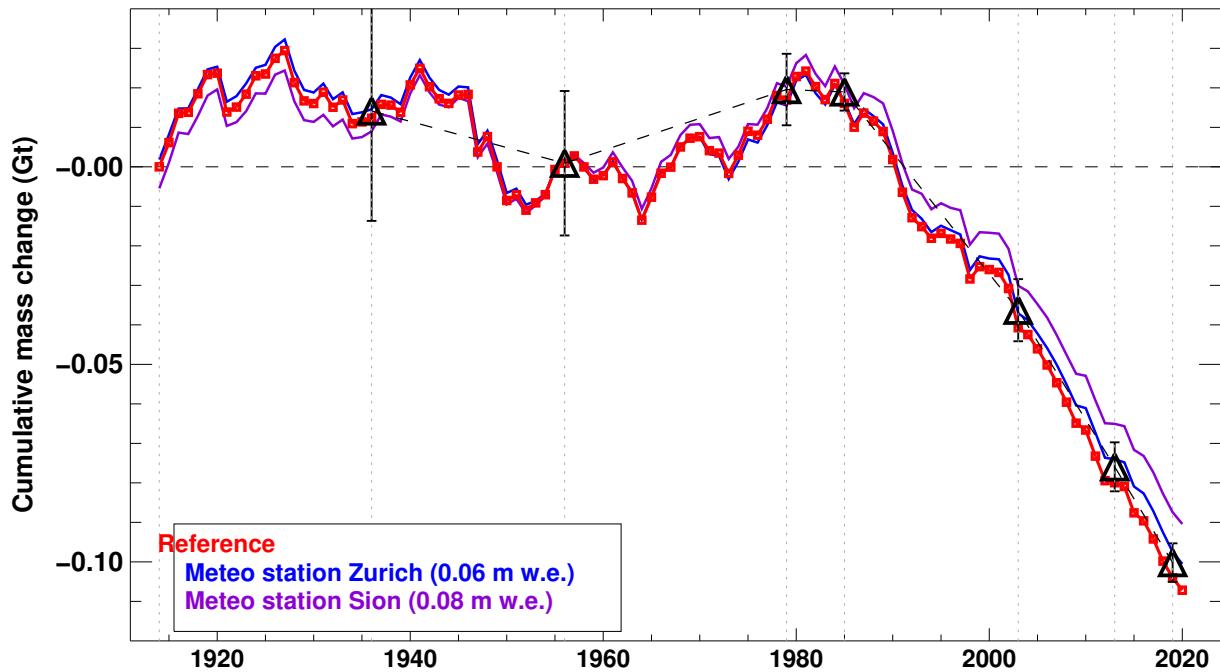

Supplementary Fig. 4. Photographic views of the ice cliff in 1935, 2011 and 2016, respectively. The present condition of the ice cliff qualitatively indicates that only parts are still subject to active frontal break-off. Photos: swisstopo, K. Luetzeler, G. Eigenmann.

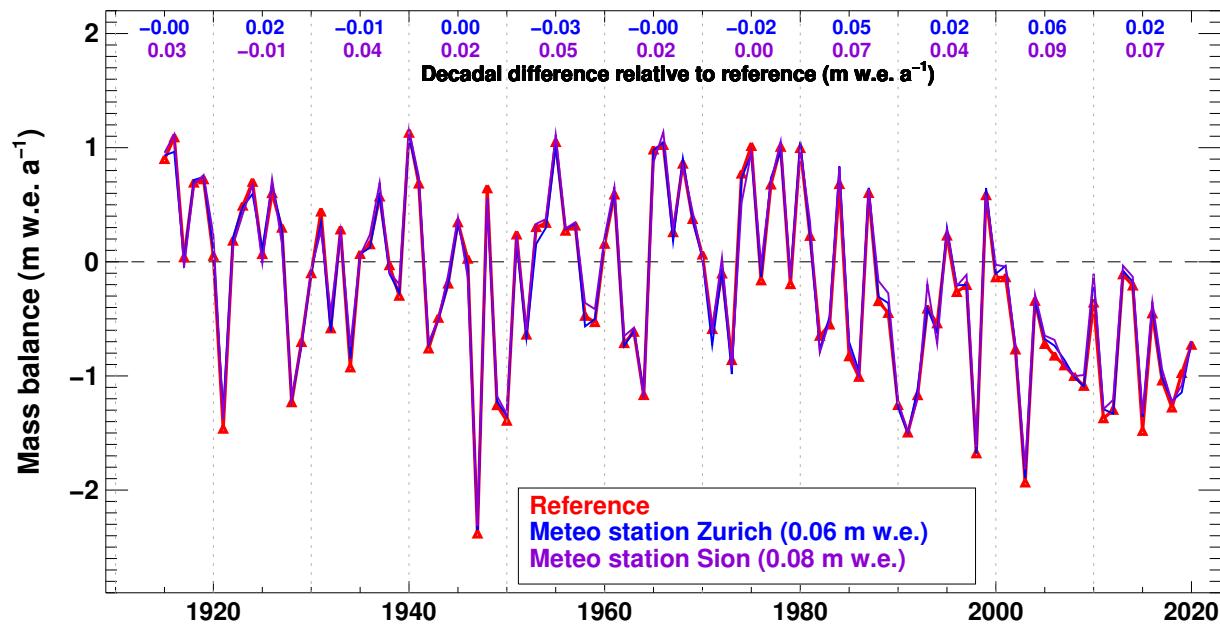

Supplementary Fig. 5. Estimated annual contribution of frontal ice break-off to the overall mass loss by melting. The solid line refers to an 11-year running mean. The timing of major geometrical changes in the ice cliff (see also Fig. 5 of main text) is indicated (bottom).

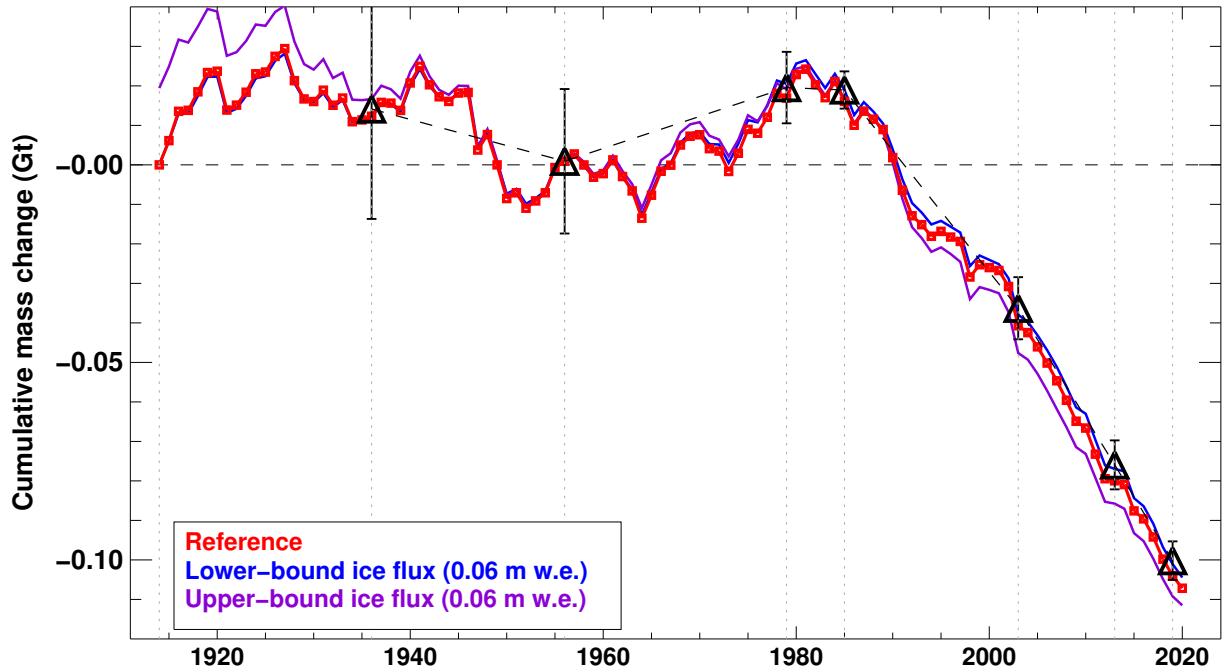

Supplementary Fig. 6. Estimated uncertainty for every individual annual point mass balance observation during the period 1914-2020 for (a) the upper measurement site, (b) the lower site, and (c) for the combined point uncertainty of all measurements per year. Thick lines correspond to 11-year running means and are shown for all panels in (c) for comparability. Symbols indicate the type of the observation that has been used to assign specific uncertainties. See main text for details on estimating the uncertainty of point mass balance measurements.

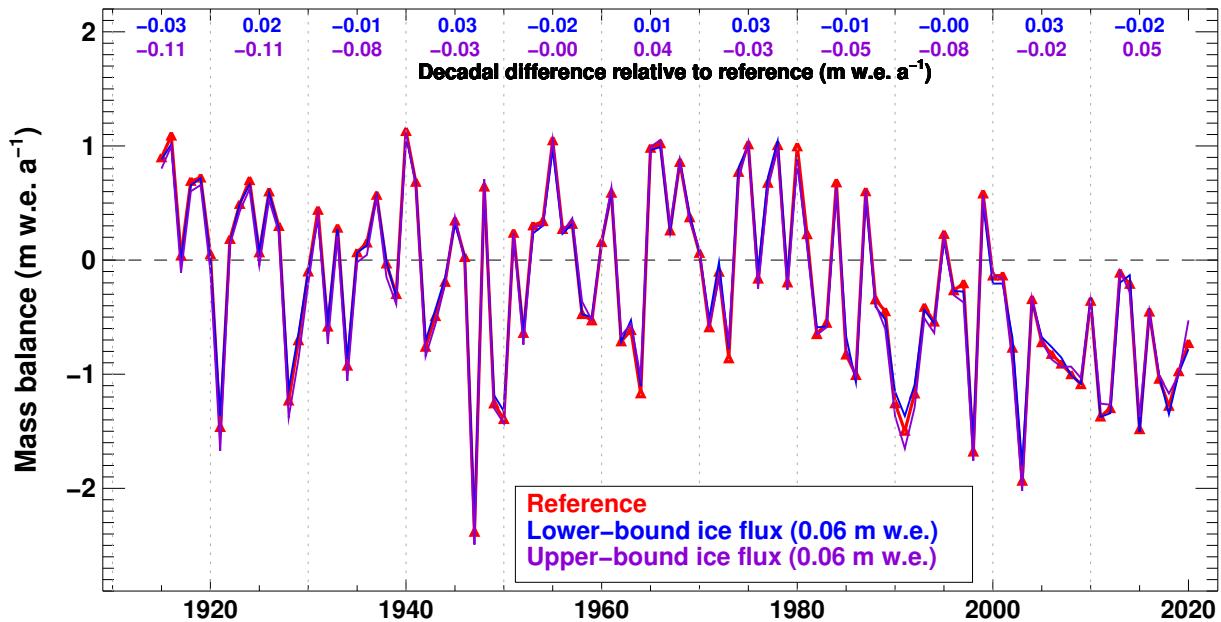

Supplementary Fig. 7. Cumulative annual mass change of Claridenfirn 1914-2020 for the reference (red) and experiments relying on meteorological time series from distant stations and geodetic mass changes based on DEMs including error bars (black triangles). Cumulative mass changes are shown relative to the year 1956 for all curves.

Supplementary Fig. 8. Annual mass balance series of Claridenfirn 1914-2020 based on the reference result and experiments relying on meteorological time series from distant stations. Numbers on top indicate differences in average decadal mass balance (in m w.e. a⁻¹) between the reference and the individual experiments. The standard deviation of annual mass balances 'experiment minus reference' over the entire time period is given in brackets.

Supplementary Fig. 9. Cumulative annual mass change of Claridenfirn 1914–2020 for the reference (red) and two experiments prescribing lower and upper bound maximum uncertainties in frontal ice break-off (see main text for details). Geodetic mass changes based on DEMs are shown including error bars (black triangles). Cumulative mass changes are relative to the year 1956 for all curves.

Supplementary Fig. 10. Annual mass balance series of Claridenfirn 1914–2020 based on the reference result and two experiments prescribing lower and upper bound maximum uncertainties in frontal ice break-off (see main text for details). Numbers on top indicate differences in average decadal mass balance (in m w.e. a^{-1}) between the reference and the individual experiments. The standard deviation of annual mass balances 'experiment minus reference' over the entire time period is given in brackets.

Supplementary Table 1. Time series of winter (b_w) and annual (b_a) mass balance in mm w.e. at the **lower** measurement site on Claridenfirn (≈ 2700 m a.s.l.) during the period 1914 to 2020. The type of mass balance measurements is indicated by the abbreviations P for stake reading, H for marked horizon and S for snow depth probing. ρ_w and ρ_a report density (in kg m^{-3}) during the spring and the late-summer survey, respectively. Regular fonts refer to measured values. Italic fonts indicate measurements which are subject to higher uncertainty, and no values are stated for missing data although the dates of field surveys are known.

Supplementary Table 2. Time series of winter (b_w) and annual (b_a) mass balance in mm w.e. at the upper measurement site on Claridenfirn (≈ 2900 m a.s.l.) during the period 1914 to 2020. The type of mass balance measurements is indicated by the abbreviations P for stake reading, H for marked horizon and S for snow depth probing. ρ_w and ρ_a report density (in kg m^{-3}) during the spring and the late-summer survey, respectively. Regular fonts refer to measured values. Italic fonts indicate measurements which are subject to higher uncertainty, and no values are stated for missing data although the dates of field surveys are known.

Supplementary Table 3. Qualitative assessment of the evolution of the ice cliff, the situation in the depositional zone of avalanches and potential mass losses by ice avalanches based on topographical maps and aerial photographs of the Federal Office of Topography. L_{cliff} refers to the width of the cliff subject to frontal ice break-off.

Year	L_{cliff}	Remarks
1914	800 m	Fully connected glacier tongue over the underlying 500 m, average slope $31^\circ \Rightarrow$ substantial losses by ice avalanches rather unlikely, but possible
1956	420 m	Fully connected glacier tongue over the underlying 350 m, average slope $33^\circ \Rightarrow$ losses by ice avalanches likely
1985	500 m	Partly connected glacier tongue over the underlying 300 m, average slope $28^\circ \Rightarrow$ losses by ice avalanches likely
1997	750 m	Glacier tongue disconnected from ice fall, small remnant / avalanche-fed glacier (0.07 km^2) below main ice cliff, average slope 24° ; lateral glaciers below ice cliff are still connected \Rightarrow losses by ice avalanches likely
2013	480 m	Glacier tongue fully disconnected from ice fall, two very small remnant / avalanche-fed ice patches ($0.01-0.02 \text{ km}^2$) below main ice cliff; the main ice cliff has significantly lost in height \Rightarrow losses by ice avalanches possible, but limited

Supplementary Table 4. Mass balance glaciers in the European Alps, ordered according to country and alphabet. The present area of all glaciers, the total period with observations, as well as the average mass balance in the two periods 1968–2018 (if available), and 2008–2018 is given (see Figure 12 of main text). All data have been provided by the World Glacier Monitoring Service.
