

Supplementary Table: Flagellar transformation in eukaryotic groups. Historically it has been reported that the location of the oldest flagellum (anterior or posterior) is of phylogenetic value. While the strength of evidence is variable in different studies, the information available in the published literature suggests that nearly all eukaryotes studied have the “bikont” pattern, and relatively few have the “unikont” pattern. In cases where there are more than two flagella, or anterior/ posterior is not an obvious distinction between the two flagella, it is not really possible to judge whether the pattern is bikont or unikont. Ultimately, it will be necessary to examine the ontogeny of flagella at a molecular genetic level to understand which flagella are homologous.
