Socioeconomic Status, Individual Behaviors and Risk of Mental disorders: A Mendelian Randomization Study

Corresponding to: Ying Peng. Department of Neurology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou 510120, China. Email: pengy2@mail.sysu.edu.cn. Telephone: 86-13380051581.

Supplementary Introduction for the Mendelian Randomization Approach

In recent years, the Mendelian randomization (MR) approach is widely applied to explore the risk factors of diseases (Smith and Ebrahim, 2003). The concept of MR was firstly attributed to Katan in 1986 and subsequently developed by the others, with instrumental variables (IVs) in econometrics introduced (Katan, 1986). In the MR framework, genetic variants are used as IVs to represent the exposure phenotypes of interest. When a certain phenotype is determined by the genotype, and the phenotype leads to the onset of a certain disease, then it can be considered that the genotype affects the disease through the phenotype (Thomas and Conti, 2004). Based on the random assortment at meiosis and fixed allocation at conception for genetic variants, MR design is less vulnerable to bias from confounders and reverse causality. Thus, genetic variations (single nucleotide polymorphisms, SNPs) can be used as IVs to infer causal relationships between phenotypes and the risk of diseases (Burgess et al., 2013). IVs must meet the following three assumptions in the MR framework: i) IVs are robustly associated with the exposure phenotype; ii) IVs are not associated with any potential confounders; iii) IVs influence the outcome only through the exposure phenotype (Emdin et al., 2017). The first assumption is known as the "relevance" assumption. The second (the "exclusiveness" assumption) and third (the "independence" assumption) assumptions are collectively known as independence from horizontal pleiotropy. Horizontal pleiotropy is also called "biological pleiotropy", which refers to an SNP associated with multiple exposure phenotypes and affecting the outcome independent of the risk factor but through other pathways. Violation of the fundamental assumptions can introduce bias in the MR analysis. To meet the first assumption, SNPs should be strongly associated with the exposure phenotype at genome-wide significance ($p < 5 \times 10^{8}$) with sufficient statistical strength (F-statistics > 10) (Burgess and Thompson, 2011). Whereas for the second and third assumptions, an array of sensitivity analysis methods have been established to evaluate any potential pleiotropy. For example, the intercept derived from MR-Egger regression can be used to detect horizontal pleiotropy. More detailed, the intercept with a $p > 0.05$ suggests the rejection of the "non-zero intercept" hypothesis, indicating no pleiotropy detected (Burgess and Thompson, 2017).

The present work performed a two-sample MR (TSMR) analysis based on summary-level statistics from genome-wide association studies (GWAS). The minimum information required for TSMR analysis includes SNP identification (ID), effect-allele (EA), effect size (BETA), and standard error (SE) of BETA. Other non-essential but useful information for MR analysis includes other-allele (OA), effect allele frequency (EAF), p-value, sample size (N), and so on. In our study, four models were used to estimate the causality including inverse weighted variance (IVW), MR-Egger regression, weighted median and weighted mode estimation. Detailed instructions for each of the models were presented in Table S6. Rigorous SNPs quality control and complementary statistical methods were conducted to detect and correct any potential pleiotropy.

Table S1. Previous studies investigating associations between socioeconomic status/individual behaviors and mental disorders.

Exposures	Mental disorders	Type of study	PMID	Primary Results
Education level	Major depressive disorder	Cohort study	25605025	Low educational level was associated with increased risk of major depressive disorder.
Educational attainment	Bipolar disorder	Case-control	16524631	Increased educational attainment was associated with increased risk of bipolar disorder.
Family income	Major depressive disorder	Cohort study	29450462	Low family income level was associated with increased risk of major depressive disorder.
Sugar-sweetened beverage consumption	Clinical depression or depressive symptoms	Meta-analysis	30419536	Regular consumption of sugar-sweetened beverage was associated with increased risk of depression.
Physical activity levels	Clinical depression or depressive symptoms	Meta-analysis	29690792	Higher physical activity level was associated with reduced risk of depression.
Physical activity level	Anxiety symptoms	Meta-analysis	31542132	Higher physical activity level was associated with reduced risk of anxiety symptoms.
Tobacco smoking behaviors	Bipolar disorder	Case-control	19267698	Bipolar disorder was associated with higher prevalence of tobacco smoking behaviors.
Smoking status (current, former and never)	Depression	Meta-analysis	24935795	Smoking was associated with increased risk of depression relative to both never smokers and former smokers
Smoking status (smoker or nonsmoker)	Schizophrenia	Meta-analysis	30102383	Smokers had an increased risk of schizophrenia compared with nonsmokers
Alcohol consumption (abstinence, light, moderate and heavy drinking)	Depressive symptoms	Meta-analysis	31837230	Light drinking was associated with lower risk of depressive symptoms while heavy drinking was not associated with depressive symptoms.
Sleep quality	Bipolar disorder	Cohort study	26228404	Poor sleep quality was associated with increased risk of bipolar disorder
Sedentary behaviors	Clinical depression or	Meta-analysis	25183627	Higher sedentary behavior at baseline was associated with

	depressive symptoms			higher risk of depression
Number of sexual partners	Depressive symptoms	Cohort study	21590465	Increased number of sexual partners was associated with increased risk of depressive symptoms.
Driving speed	Schizophrenia	Case-control	30219605	Patients with schizophrenia drove slower than healthy controls.
Age at first birth	Depressive symptoms	Cohort study	11989963	Delaying first birth was associated with decreased risk of depressive symptoms.

Table S2. Detailed description of exposure phenotypes in the present study.

Phenotypes	PMID	Sample size	Ancestry	Definition
Socioeconomic status				
Education attainment	30038396	1,131,881	European	Education attainment was measured as number of years of schooling completed. Mean education years 16.8 ± 4.2. (SSGAC: 10k lead SNPs in the sample including 23andMe; full GWAS data was available only from the sample excluding 23andMe.)
Total household income before tax	31844048	286,301 (Male 48.35%)	European	Using a 5-point scale corresponding to the total household income before tax: 1 being less than £18,000, 2 being £18,000-£29,999, 3 being £30,000-£51,999, 4 being £52,000-£100,000 and 5 being greater than £100,000. This 5-point scale was analyzed by treating the categories of income as a continuous variable. (UKB: top SNPs reported in the original GWAS; full GWAS data was no available.)
Dietary composition				
Relative carbohydrate intake	32393786	268,922 (Male 39.44%)	European	Carbohydrate included intake from all saccharides, while sugar included intake from mono- and disaccharides only. The four dietary composition phenotypes were measured as relative intake, which could be described as an "adjusted macronutrients density". Specifically, phenotype definition of the energy-corrected macronutrient intakes is given by $$corrected\ intake = \frac{energy\ from\ macronutrient}{total\ energy^{\beta}}$$ Here, the macronutrient and total energy intake was measured in the same unit (e.g., kilocalories). β is a correction factor and detailed estimated procedure was described by Meddens et al.
Relative fat intake	32393786	268,922 (Male 39.44%)	European	
Relative protein intake	32393786	268,922 (Male 39.44%)	European	
Relative sugar intake	32393786	235,391 (Male 43.32%)	European	
Habitual physical activity (UKB: top SNPs reported in the original GWAS; full GWAS data was not available.)				
Average acceleration	29899525	91,084	European	Average acceleration was derived from up to seven days of accelerometer wear (27.98±8.14 milli-gravities). Genetic variants used in our studied were obtained from a recent MR study (PMID: 32680943).

Moderate to vigorous physical activity (MVPA)	29899525	377,234	European	This is a self-reported phenotype measured as a continuous variable (metabolic-equivalent minutes per week: 1,650±2,084 minutes). Specifically, it was measured by taking the sum of total minutes/week of moderate physical activity (MPV) multiplied by four and the total minutes/week of VPA multiplied by eight, corresponding to their metabolic equivalents. Genetic variants proxied for MVPA were obtained from the full adjusted model without standard error (se) released. Hence, we calculated the standard error using the following formula: $se = 1/\sqrt{2N * EAF(1-EAF)}$, where N is the sample size and EAF is the effect allele frequency of SNP (PMID: 29892602).
Vigorous physical activity (VPA)	29899525	261,055 (98,060 cases vs. 162,995 controls)	European	This is a self-reported phenotype measured as a binary phenotype (98,060 cases with VPA for ≥ 3 days per week vs. 162,995 controls with VPA for 0 day per week). Participants were asked: "In a typical week, how many days did you do 10 minutes or more of vigorous physical activity? (These are activities that make you sweat or breathe hard such as fast cycling, aerobics, heavy lifting)". Genetic variants proxied for VPA were obtained from the full adjusted model without standard error (se) released. Hence, we calculated the standard error using the following formula: $se = \sqrt{[p \times (1-p)]}/\sqrt{2N \times EAF(1-EAF)}$, where p is the proportion of cases with VPA for ≥ 3 days per week, N is the sample size and EAF is the effect allele frequency of SNP (PMID: 29892602).
Smoking behaviors				
Age of initiation of regular smoking	30643251	341,427	European	Participants were asked "At what age did you begin smoking regularly?" or "what is your current age and how long have you smoked?".
Cigarettes per day	30643251	337,334	European	This phenotype was measured as the average number of cigarettes smoked per day. Participants were asked "How many cigarettes do you smoke per day?" or "How many cigarettes did you smoke per day?".
Smoking cessation	30643251	547,219	European	This phenotype was measured as binary variable with current smokers

				coded as “2” and former smokers coded as “1”. Participants were asked “Do you currently smoke? And have you ever smoked regularly?”, “Do you smoke? And have you smoked over 100 cigarettes in your entire life?”
Smoking initiation	30643251	1,232,091	European	This phenotype was measured as binary variable with ever being a regular smoker in their life (current or former) coded as “2” and never being a regular smoker in their life coded as “1”. Participants were asked “Have you smoked over 100 cigarettes over the course of your life?”, “Have you ever smoked every day for at least a month?” or “Have you ever smoked regularly?”.
Drinking behaviors				
Alcohol consumption per week	30643251	941,280	European	This phenotype was measured as the average number of drinks a participant reported drinking each week, aggregated across all types of alcohol. Participants were asked “In the past week, how many alcoholic beverages did you have?” or “Thinking about the past year, on the average how many drinks did you have each week?”.
AUDIT	30336701	121,604 (Male 43.8%)	European	The Alcohol Use Disorder Identification Test (AUDIT) total score was created by taking the sum of items 1-10 for all participants. (UKB + 23andMe: 10k SNPs; full GWAS data was not publicly available)
Sleeping behaviors				
Insomnia	30804565	1,331,010 (Male 48.98%; 397,956 cases vs. 933,054 controls)	European	UK biobank phenotype: Participants were asked “Do you have trouble falling asleep at night or do you wake up in the middle of the night?” and were able to choose one of the following four answers: “never/rarely”, “sometimes”, “usually”, or “prefer not to answer”. Insomnia cases were defined as participants who answered this question with “usually”, while participants answering “never/rarely” or “sometimes” were defined as controls. 23andMe phenotype:

				Insomnia cases affirmed at least one of the following questions: "Have you ever been diagnosed with, or treated for: Insomnia?"; “Have you ever been diagnosed with, or treated for, any of the following conditions: Insomnia but not Narcolepsy, Sleep apnea or Restless leg syndrome”; "Has a doctor ever told you that you have any of these conditions: Insomnia (difficulty getting to sleep or staying asleep)?"; "Have you ever been diagnosed by a doctor with any of the following neurological conditions: Sleep disturbance"; "Do you routinely have trouble getting to sleep at night?"; "What sleep disorders have you been diagnosed with? Please select all that apply: Insomnia, trouble falling or staying asleep"; "Have you ever taken these medications? Prescription sleep aids"; "In the last 2 years, have you taken any of these medications? Prescription sleep aids". (UKB + 23andMe: top SNPs reported in the original GWAS; full GWAS data was only available from the sample excluding 23andMe.)
Long sleep duration	30846698	339,926 (Male 43.9%; 34,184 case vs. 305,742 controls)	European	Long sleep duration was defined as sleeping for 9h or more relative to 7-8h sleep duration (set as controls).
Short sleep duration	30846698	411,934 (Male 46.9%; 106,192 cases vs. 305,742 controls).	European	Short sleep duration was defined as sleeping for 6h or less relative to 7-8h sleep duration (set as controls).
Sleep duration	30846698	446,118 (Male 45.9%)	European	Sleep duration was treated as a continuous variable. Participants were asked: About how many hours sleep do you get in every 24h? (please include naps), with responses in hour increments. Extreme responses of

				less than 3 h or more than 18h were excluded and “Do not know” or “Prefer not to answer responses” were set to missing. Mean sleep duration was 7.2±1.1 hours.
Leisure sedentary behaviors (UKB: top SNPs reported in the original GWAS; full GWAS data was not publicly available**)**				
Computer use time	32317632	422,218 (Male 45.7%)	European	Participants were asked “In a typical day, how many hours do you spend using the computer?”. Average time using the computer was 1.0 ± 1.2h.
Television watching time	32317632	422,218 (Male 45.7%)	European	Participants were asked “In a typical day, how many hours do you spend watching TV?”. Average time watching TV was 2.8 ± 1.5h.
Drive time	32317632	422,218 (Male 45.7%)	European	Participants were asked “In a typical day, how many hours do you spend driving?”. Average time driving was 0.9 ± 1.0h.
Risky behaviors (SSGAC: top SNPs reported in the original GWAS; full GWAS data for adventurousness was not available**)**				
Adventurousness	30643258	557,923	European	Participants were asked “if forced to choose, would you consider yourself to be more cautious or more adventurous? 1) Very cautious /2) Somewhat cautious /3) Neither /4) Somewhat adventurous /5) Very adventurous”.
Automobile speeding propensity	30643258	404,291	European	Participants were asked “How often do you drive faster than the speed limit on the motorway?”. Response options: 1) Never/rarely, 2) Sometimes, 3) Often, 4) Most of the time, and also 5) Do not drive on the motorway. Average normalized automobile speeding propensity was 0.04 ± 0.82. Those not driving on the motorway were dropped.
General risk to tolerance	30643258	939,908	European	The UKB measurement of general risk tolerance was based on the question “Would you describe yourself as someone who takes risks? Yes/No”. The 23andMe measurement was based on a question about overall comfort taking risks, with five response options ranging from “very comfortable’” to “very uncomfortable”.
Number of sexual partners	30643258	370,711	European	Participants were asked “About how many sexual partners have you had in your lifetime?”. If respondents reported more than 99 lifetime sexual partners, they were asked to confirm their responses. Average number of

				sexual partners was 0.03 ± 0.94.
Reproductive behaviors (SSGAC: top SNPs reported in the original GWAS; full GWAS data was only available from the sample excluding 23andMe.)				
Age at first birth (AFB)	27798627	251,151 (Male 20.33%)	European	Age at first birth (AFB): Self-reported age when subjects had their first child. In most cohorts this was asked directly like "How old were you when you had your first child?". Besides, it could also be calculated based on survey questions such as the date of birth of the subject and date of birth of the first child. The average age was 26.8 ± 4.78 years. Number of children ever born (NEB): Self-reported number of children. Participants were asked directly (e.g. "How many children do you have?" or "How many natural (biological) children have you ever had, that is, all children who were born alive?", or "How many children have you had - not counting any step, adopted, or foster children, or any who were stillborn?") . Besides, it could also be calculated based on survey questions such as pregnancy histories and outcomes, number of deliveries and so on. The average number was 2.3 ± 1.43 children. Standard error (se) of estimated genetic effect on AFB and NEB was not released by Barban et al. As AFB and NEB were analyzed as continuous variables, standard error was calculated using the following formula: $se = 1/\sqrt{2N * EAF(1-EAF)}$, where N is the sample size and EAF is the effect allele frequency of SNP (PMID: 29892602).
Number of children ever born (NEB)	27798627	343,072 (Male 31.57%)	European	

SSGAC, Social Science Genetic Association Consortium; SNP, single nucleotide polymorphism; GWAS, genome-wide association study; UKB, United Kingdom Biobank;

Table S3. Detailed descriptions for GWAS meta-analysis of 3 mental disorders.

Mental disorders	Bipolar disorder	Major depressive disorder	Schizophrenia
Samples	PGC1 and PGC2 (totally 32 samples)	PGC29, deCODE, Generation Scotland, GERA, and iPSYCH (totally 33 samples)	PGC1, new CC and East Asia (totally 49 samples)
Total sample sizes	20,352 cases/31,358 controls	45,396 cases/97,250 controls	34,241 cases/45,604 controls
Percentage of European	100%	100%	93.5%
Diagnosis criteria	Using structured diagnostic instruments, a lifetime diagnosis of bipolar disorder was established on the basis of international consensus criteria (DSM-IV or ICD-9/10). Assessments came from trained interviewers, clinician-administered checklists or medical record review.	Cases ascertainment included structured diagnostic interviews, national inpatient electronic records and Kaiser Permanente Northern California Healthcare electronic medical records (1995-2013). Lifetime major depressive disorder was diagnosed according to DSM-III/IV or ICD-9/10.	Diagnosis of schizophrenia was established on the basis of DSM-IV or ICD-10. All participating cohorts were further included for GWAS meta-analysis based on a questionnaire covering assessment protocol and associated quality control procedures.

GWAS, genome-wide association study; PGC, Psychiatric Genomics Consortium. New CC, case-control samples not part of a discovery portion of a prior PGC mega-analysis; iPSYCH, Integrative Psychiatric Research; DSM, Diagnostic and Statistical Manual of Mental Disorders; ICD, International Classification of Diseases.

Table S4. Details of SNPs filtering procedures.

Exposure phenotypes	Number of SNPs available[1]	SNP filtering (number of SNPs remained[2])									
		Step 1	BIP			MDD			SCZ		
			Step 2	Step 3	Step 4	Step 2	Step 3	Step 4	Step 2	Step 3	Step 4
Socioeconomic status											
Educational attainment	393	386	385	371	364	385	371	369	380	367	347

SNP, single nucleotide polymorphisms; BIP, bipolar disorder; MDD, major depressive disorder; SCZ, schizophrenia.

[1] Number of independent SNPs ($p < 5 \times 10^{-8}$) within each phenotype at a cut-off of linkage disequilibrium $r^2 \leq 0.001$.

[2] SNPs filtering steps:

Step 1, we excluded SNPs associated with more than one phenotype.

Step 2, we extracted exposure-SNPs from the outcomes and excluded the SNPs meeting the following items: 1) SNPs associated with outcomes at genome-wide significance; 2) SNPs absent in the outcome GWAS data without appropriate proxies available.

Step 3, we harmonized the SNPs of from exposure and outcome to exclude SNPs being palindromic with intermediate allele frequencies based on the allele frequency over 0.42 using the harmonization function in the "Two-sample MR" R package.

Step 4, we conducted MR-PRESSO to exclude SNPs with potential pleiotropy using "MR-PRESSO" R package.

Table S5. List of genetic variants associated with more than one phenotype.

SNPs	Exposures
rs1008078	educational attainment, smoking initiation
rs10189857	educational attainment, television watching time
rs1104608	relative carbohydrate intake, alcohol consumption per week
rs11076962	educational attainment, smoking initiation
rs11128203	smoking initiation, automobile speeding propensity
rs11588857	educational attainment, total household income before tax
rs11940694	alcohol consumption per week, Alcohol Use Disorder Identification Test
rs12151248	educational attainment, total household income before tax
rs12567114	short sleep duration, sleep duration
rs1260326	alcohol consumption per week, Alcohol Use Disorder Identification Test
rs13107325	alcohol consumption per week, television watching time, short sleep duration
rs1531518	general risk tolerance, number of sexual partners
rs17005118	insomnia, short sleep duration
rs205024	short sleep duration, sleep duration
rs2239030	adventurousness, general risk tolerance
rs2279829	smoking initiation, number of sexual partners
rs2472297	relative carbohydrate intake, alcohol consumption per week
rs42210	educational attainment, television watching time
rs429358	moderate to vigorous physical activity, insomnia
rs4702	insomnia, number of sexual partners
rs55745410	adventurousness, general risk tolerance
rs56113850	number of cigarettes per day, smoking cessation
rs58400863	smoking initiation, general risk tolerance
rs62062288	alcohol Use Disorder Identification Test, automobile speeding propensity
rs62519839	adventurousness, general risk tolerance
rs67361341	adventurousness, general risk tolerance

rs6874731	smoking initiation, general risk tolerance
rs7012814	relative fat intake, Relative sugar intake
rs72780746	smoking initiation, number of sexual partners
rs8097672	relative carbohydrate intake, relative sugar intake
rs838144	relative carbohydrate intake, relative sugar intake
rs9372625	computer use time, automobile speeding propensity
rs9556958	educational attainment, adventurousness
rs984409	computer use time, television watching time

SNP, single nucleotide polymorphisms.

Table S6. Descriptions of the Mendelian randomization (MR) methods.

Mendelian randomization methods	Intercept	Breakdown levels	Assumptions and comments
Inverse variance weighted (IVW)	Zero	0%	Instrumental variants (IVs) should meet the Instrument Strength Independent of Direct Effects (InSIDE) assumption. The method assumes that all the variants are valid. Even one invalid IV can bias the effect estimate. This method is the most powerful and precise.
MR-Egger regression	Non-zero	100%	IVs should meet the InSIDE assumption. This method allows all IVs are invalid but it is substantially less efficient than IVW and median-based methods. A non-zero intercept derived from Egger regression can be used to determine whether there is directional pleiotropy detected.
Weighted median	Zero	50%	This method allows no more than 50% of invalid IVs and the efficiency is similar to that of IVW.
Weighted-mode based estimation	Zero	50-100%	This method allows more than 50% of invalid IVs. The efficiency is smaller the IVW and weighted median methods, but is larger than that of MR Egger regression.

Table S7. Mendelian randomization estimates for the association of socioeconomic status/individual behaviors with 3 mental disorder derived from different models.

Exposures	Outcomes	Number of SNPs	Number of proxies[1]	Inverse variance weighted		MR-Egger		Weighted median		Weighted mode	
				OR (95% CI)	*p*	OR (95% CI)	*p*	OR (95% CI)	*p*	OR (95% CI)	*p*

BIP, bipolar disorder; MDD, major depressive disorder; SCZ, schizophrenia.

R^2 presented the proportion of variance in exposure phenotypes explained by single nucleotide polymorphisms (SNPs) using the formula $R^2 = [2 \times BETA^2 \times EAF \times (1 - EAF)]/[2 \times BETA^2 \times EAF \times (1 - EAF) + 2 \times SE(BETA)^2 \times N \times EAF \times (1 - EAF)]$. Here, BETA is the genetic effects on exposures; EAF is effect allele frequency; SE(BETA) is standard error of the genetic effects; N is the sample size. *F*-statistic quantified the strength of each selected SNP using the formula $R^2 \times (N - 2)/(1 - R^2)$.

Table S9. Heterogeneity and pleiotropy assessment for significant results ($p < 0.05$).

BIP, bipolar disorder; MDD, major depressive disorder; SCZ, schizophrenia.

Table S10. Confirmed confounders for mental disorders (BIP, MDD and SCZ) from previous Mendelian randomization studies.

Outcomes	Confounders
BIP	Except for adventurousness, insomnia, smoking initiation and educational attainment identified in the present study, following factors have been confirmed: C-Reactive Protein (PMID: 27327646) Magnesium, copper (PMID: 27327646)
MDD	Except for age at first birth, automobile speeding propensity, number of sexual partners and educational attainment identified in the present study, following factors have been confirmed: Trunk fat percentage, Arm fat percentage (right), Arm fat percentage (left), Leg fat percentage (right), Leg fat percentage (left), Trunk fat mass, Arm fat mass (right), Arm fat mass (left), Leg fat mass (right), Leg fat mass (left), body mass index (BMI), weight, Body fat percentage, Body fat mass (PMID: 31383844) statin and PCSK9 inhibitor therapy (PMID: 29986042) neuroticism (PMID: 30697695) Bacilli (PMID: 33008395) intra-cellular volume fraction (PMID: 32385265) serum morning plasma cortisol level (PMID: 31474942) triglycerides, interleukin-6 (IL-6), and C-reactive protein (CRP) (PMID: 30886334) ADHD (PMID: 32249726) confiding in others, daytime napping (PMID: 32791893) testosterone (PMID: 32610558) Aminoacyl-tRNA biosynthesis (PMID: 31919502)
SCZ	Except for automobile speeding propensity, number of sexual partners, cigarettes per day and smoking initiation identified in the present study, following factor have been confirmed: Cannabis use (PMID: 28115737) C-reactive protein, sIL-6R (PMID: 29094161) fasting insulin levels (PMID: 30100396) neuroticism (PMID: 32578352) plasma total homocysteine (PMID: 26208850)

	plays computer games (PMID: 31766499) 2-methoxyacetaminophen sulfate, glycine, serine, threonine metabolism (PMID: 31919502) Enterobacteriaceae family, Enterobacteriales order, Gammaproteobacteria class (PMID: 33008395)

BIP, bipolar disorders; MDD, major depressive disorders; SCZ, schizophrenia; PMID: PubMed identifier.

Table S11. SNPs associated with confirmed confounders at genome-wide significance ($p < 5 \times 10^{-8}$).

SNP, single nucleotide polymorphisms; BIP, bipolar disorder; MDD, major depressive disorder; SCZ, schizophrenia

Table S12. Inverse variance weighted (IVW) analysis after exclusion of SNPs associated with potential confounders.

Exposures	Outcomes	IVW analysis		
		OR	95% CI	*p* values
Smoking initiation	BIP	1.59	1.37-1.86	2.34E-09
Insomnia	BIP	1.17	1.08-1.28	2.53E-04
Adventurousness	BIP	1.93	1.44-2.59	1.01E-05
Educational attainment	MDD	0.73	0.65-0.82	1.80E-07
Automobile speeding propensity	MDD	0.56	0.38-0.82	2.78E-03
Number of sexual partners	MDD	1.39	1.13-1.71	1.49E-03
Age at first birth	MDD	0.83	0.72-0.96	1.02E-02
Smoking initiation	SCZ	1.64	1.42-1.88	8.20E-12
Automobile speeding propensity	SCZ	0.42	0.28-0.65	1.04E-04
Number of sexual partners	SCZ	2.33	1.79-3.04	4.28E-10

SNP, single nucleotide polymorphisms; BIP, bipolar disorder; MDD, major depressive disorder; SCZ, schizophrenia; OR, odds ratio; CI, confidence interval.

Figure S1. Scatter plots showing robust genetic associations of socioeconomic status/individual behaviors with mental disorders.

Each of the SNPs associated with exposures is represented by a black dot with the error bar depicting the standard error of its association with a specific exposure (horizontal) and the target mental disorder (vertical). The slopes of each line represent the causal association for each Mendelian randomization method.

BIP, bipolar disorder; MDD, major depression; SCZ, schizophrenia.

Figure S2. Leave-one-out analysis for all significant causal relationships detected in primary analysis. Within each panel, the black points represent the causal estimate of association between a specific exposure and target mental disorder after discarding each SNP in turn. Red points represent the overall causal estimate using the random-effects inverse variance weighted. Horizontal lines denote 95% confidence intervals.

BIP, bipolar disorder; MDD, major depressive disorder; SCZ, schizophrenia.
