## Supplemental Materials

## Power Analysis

A Monte Carlo power analysis was run in order to determine the sample size and stimuli size needed for this experiment. A logistic mixed effects, fit to the voiced stops data from Goldrick et al. (2014) was used to create simulated data, and a statistical model was re-fitted to the simulated data to test whether the crucial interaction between language and trial type could be detected by a likelihood ratio test. Based on 1,000 simulations with a varying numbers of participants and cognate and non-cognate target items, we found that 18 participants naming 8 cognate items and 16 non-cognate items per language yielded $\beta$ exceeding 0.8 . Results for this analysis can be found in Table S1.

Table S1: Monte Carlo power analysis results

| Participants | N-Cognate | N-NonCognate | EstimatedPower |
| :--- | :--- | :--- | :--- |
| 10 | 0 | 10 | 0.416 |
| 15 | 0 | 10 | 0.523 |

## Stimulus norming

All of the target pictures were normed in two different norming tasks. The first norming task asked participants to give a one word label to each picture. Ten native Spanish speakers from Mexico and 11 native English speakers from the U.S. were recruited on Prolific (prolific.ac). One of the English participants had to be excluded because they mislabeled all pictures. Participants gave most of the pictures either the target label or a semantically related label. The only picture that was consistently mislabeled by Spanish participants was the picture for texto (text in English). This lead us to change that target word to telephone (teléfono in Spanish). The second norming task asked participants to rate the label given to each picture from not acceptable at all (1) or very acceptable (10). Ten native Spanish speakers from Mexico and 10 native English speakers from the U.S. were recruited on Prolific (prolific.ac). All of the pictures received scores of 7.8 or higher in both languages, suggesting that the target labels are appropriate for the pictures.

## Filler items

Regular fillers

| Non-cognate: English | Non-cognate: Spanish | Cognate: English | Cognate: Spanish |
| :--- | :--- | :--- | :--- |
| yarn | estambre | lion | leon |
| apple | manzana | mango | mango |
| raccoon | mapache | elephant | elefante |
| leaf | hoja | giraffee | jirafa |
| moon | luna |  |  |
| watermelon | sandía |  |  |
| shoe | zapato |  |  |
| strawberry | fresa |  |  |

Note: English translation for Non-cognate: Spanish words and Cognate: Spanish words are in corresponding Non-cognate: English and Cognate: English rows respectively.

Other language fillers

| Other language: English | Other language: Spanish |
| :--- | :--- |
| beak | castor (beaver) |
| floor | playa (beach) |
| mustache | pavo real (peacock) |
| library | tetera (teapot) |
| shark | babero (bib) |
| scissors | cerdo (pig) |
| drawing | platos (dishes) |
| pendant | boleto (ticket) |
| dog | tocino (bacon) |
| fish | repostería (pastry) |
| frosting | margarita (dasiy) |
| eggplant | mesa (table) |
| keyboard | cama (bed) |
| roof | chile (pepper) |
| finger | escritorio (desk) |
| breakfast | examen (test) |

Note: English translation for Other language: Spanish words are in parentheses.

## Degree of diphthongization and monophthongization of /e/

A linear mixed-effects model was run to examine the F1 of /e/ as a dependent variable on time point ( 20 versus 80 percent vowel duration). Our fitting procedure yielded two sets of correlated random effects factors: (1) by participants with a random intercept and single versus mix and language as random slopes and (2) by word with a random intercept and single versus mix as a random slope. Within each set, random effects were correlated.

As shown in Figure S1, bilinguals successfully switched between their two languages, with English /e/ produced with a lower, more English-like F1 than Spanish ( $\beta=63.2$, SE $\beta=$ $17.45, \mathrm{t}=3.62, \mathrm{p}<0.01$ ). They also produced vowels with F 1 significantly differently between the two time points $(\beta=-22.48, S E \beta=9.58, \mathrm{t}=-2.46, \mathrm{p}<0.001)$. There was a significant
interaction between time point and language ( $\beta=67,7, S E \beta=2.78, \mathrm{t}=-24.78, \mathrm{p}<0.001$ ), indicating that the F1 of/e/ was produced differently depending on whether it was produced in Spanish or English at 20 or 80 percent vowel duration. However, there was no indication of an increase or decrease of diphthongization depending on whether bilinguals were mixing ( $\beta=4.93$, $S E \beta=4.03, \mathrm{t}=1.22, \mathrm{p}>0.05)$ or switching $(\beta=-0.07, S E \beta=1.76, \mathrm{t}=-0.04, \mathrm{p}>0.05)$ between their languages. Overall, these results indicate that there are no mixing or switching costs with regards to the degree of diphthongization and monophthongization of /e/. There were no other main effects, two way interactions, or three way interactions. More details about the fixed effects of this model can be found in Table S2.
