## A. Samples

## A.1. Selection Rules

We define as mainstream parties all parties of the social democratic, christian democratic, conservative and liberal party families that attracted at least $5 \%$ of the popular vote in a given election. Our codings are vastly based on the classifications of the MARPOR project. However, we deviate in couple of instances. In particular, we classify the Finnish Centre Party (KESK) and the Swedish Centre Party (C) as liberal parties instead of agrarian parties, which is in line with their core ideology and their group affiliation in the European Parliament.

Our definition of radical right parties follows the widely used approaches put forward by Mudde (2007) and Art (2011), who define (populist) radical right parties in terms of both substantive/positional ideological features (nativism) and non-positional ideological features (populism or anti-elitism). While our study purely focuses on the positional or programmatic appeal of the radical right, this definition allows for the inclusion of parties sometimes treated as 'borderline' cases in the extant literature, such as the British UK Independence Party (UKIP) or the Norwegian Progress Party (Mudde 2007). While these parties may vary in the intensity and kind of their nativist appeals, they still serve as functional equivalents within their national party systems (Mudde 2016).

## A.2. Macro Study

| Country | Year | Mainstream Parties | MSP \% Votes | RRP \% Votes |
| :---: | :---: | :---: | :---: | :---: |

## B. Measures

## B.1. Party Positions

Considerable methodological debates surround the use of MARPOR data (see e.g. Benoit, Laver, and Mikhaylov 2009; Meyer 2013; Adams et al. 2019). Nevertheless, party programs are often the product of intense intra-party debates and should, thus, provide reliable estimates of parties' policy orientations. Moreover, they remain the only data covering time periods sufficient to investigate parties' policy positions in a long-term perspective, which increases the credibility of our analyses. Similarly to existing approaches in the literature (e.g. Abou-Chadi 2016), we focus on a specific subset of MARPOR items to approximate party positions on immigration. We follow the established procedure of retrieving party positions as a weighted aggregate of positive and negative statements in their manifestos (e.g. Budge 2001). Specifically, we follow the approach detailed in Lowe et al. 2011 of constructing log odds-ratio scales from positive and negative references to distinct political issues, which acknowledges that additional positive or negative statements in manifestos are more weighty in informing voters about a party's policy position when the overall number of statements on an issue is low and when the ratio between positive and negative statements is balanced.

Using this scaling approach, we calculate three different measures of party positions that gauge mainstream parties' stances on the radical right's core issue domain:

## - National identity

- Data: This measure is based on data from the MARPOR Project (Volkens et al. 2019), which covers nearly all mainstream parties in a given election.
- Items: per601 (National way of life: positive), per602 (National way of life: negative), per607 (Multiculturalism: positive) and per608 (Multiculturalism: negative)
- Party positions:

$$
\operatorname{pos}_{p^{j}}=\log \left(N_{p^{j}}^{601}+N_{p^{j}}^{608}+.5\right)-\log \left(N_{p^{j}}^{602}+N_{p^{j}}^{607}+.5\right)
$$

- Party salience scores:

$$
\operatorname{sal}_{p^{j}}=\log \left(N_{p^{j}}^{601}+N_{p^{j}}^{602}+N_{p^{j}}^{607}+N_{p^{j}}^{608}+1\right)-\log \left(N_{p^{j}}^{\mathrm{total}}\right)
$$

- Multiculturalism (Abou-Chadi 2016):
- Data: This measure is based on data from the MARPOR Project (Volkens et al. 2019), which covers nearly all mainstream parties in a given election.
- Items: per607 (Multicultarilism: positive) and per608 (Multiculturalism: negative)
- Party positions:

$$
\operatorname{pos}_{p^{j}}=\log \left(N_{p^{j}}^{608}+.5\right)-\log \left(N_{p^{j}}^{607}+.5\right)
$$

- Party salience scores:

$$
\operatorname{sal}_{p^{j}}=\log \left(N_{p^{j}}^{607}+N_{p^{j}}^{608}+1\right)-\log \left(N_{p^{j}}^{\text {total }}\right)
$$

## - Immigration (Dancygier and Margalit 2020):

- Data: This measure is based on the novel data base Immigration in Party Manifestos (IPM) (Dancygier and Margalit 2020), which covers only the two (sometimes three) largest mainstream parties in a given election. This data set offers a detailed overview of party positions on immigration, coding, akin to the coding scheme of the MARPOR project, both negative and positive references to immigration across 30 different categories.
- Categories: Civil liberties, Culture and identity, Deportation, Economic integration, Education, Equal treatment, Gay rights, Housing, Illegal immigration, Immigration policy, Integration, Islam, Jobs, Language, Law and order, National security, Other economic, Other, Overpopulation, Religion, Slaughtering of animals, Spatial clustering, Tolerance and racism, Voting rights Wages, Welfare system, Women's issues.
- Items: For each category $k, N_{p^{j}}^{k^{+}}$gives the number of quasi-sentences with favorable references to immigration in that category while $N_{p^{j}}^{k^{-}}$gives the number of unfavorable mentions. Party positions:

$$
\operatorname{pos}_{p^{j}}=\log \left(\sum_{k=1}^{K} N_{p^{j}}^{k^{+}}+.5\right)-\log \left(\sum_{k=1}^{K} N_{p^{j}}^{k^{-}}+.5\right)
$$

- Party salience scores:

$$
\operatorname{sal}_{p^{j}}=\log \left(\sum_{k=1}^{K} N_{p^{j}}^{k^{+}}+\sum_{k=1}^{K} N_{p^{j}}^{k^{-}}+1\right)-\log \left(N_{p^{j}}^{\text {total }}\right)
$$

## - Cultural Protectionism \& Traditional Morality (Meguid 2005, 2008):

- Data: This measure is based on data from the MARPOR Project (Volkens et al. 2019), which covers nearly all mainstream parties in a given election.
- Items: per601 (National way of life: positive), per602 (National way of life: negative), per603 (Traditional morality: positive), per604 (Traditional morality: negative), per607 (Multiculturalism: positive) and per608 (Multiculturalism: negative), per605 (Law and order: positive), and per705 (underprivileged minority groups: positive),
- Party positions:

$$
\operatorname{pos}_{p^{j}}=\log \left(N_{p^{j}}^{601}+N_{p^{j}}^{603}+N_{p^{j}}^{605}+N_{p^{j}}^{608}+.5\right)-\log \left(N_{p^{j}}^{602}+N_{p^{j}}^{604}+N_{p^{j}}^{607}+N_{p^{j}}^{705}+.5\right)
$$

- Party salience scores:

$$
\operatorname{sal}_{p^{j}}=\log \left(N_{p^{j}}^{601}+N_{p j}^{602}+N_{p^{j}}^{603}+N_{p^{j}}^{604}+N_{p^{j}}^{605}+N_{p^{j}}^{607}+N_{p^{j}}^{608}+N_{p^{j}}^{705}+1\right)-\log \left(N_{p j}^{\text {total }}\right)
$$

## - Additional notes for all measures:

- $N_{p^{j}}^{i t e m}$ denotes the number of quasi-sentences in a party $p^{\text {'s }}$ manifesto for election $j$ at time $t$.
- Positional shifts are calculated as first differences: $\Delta \operatorname{pos}_{p^{j}}=\operatorname{pos}_{p^{j_{t}}}-\operatorname{pos}_{p^{j_{t-1}}}$
- Salience shifts are calculated as first differences: $\Delta \operatorname{sal}_{p^{j}}=\operatorname{sal}_{p^{j} t}-\operatorname{sal}_{p^{j_{t-1}}}$

## B.2. Moderators

- Radical right life cycle: We divide the life cycle of radical right parties into three phases: Marginalization phase, breakthrough phase, and consolidation phase.
Marginalization phase: We define radical right parties as marginal competitors with little electoral relevance when they fail to score at leat $5 \%$ of the vote in national elections. Most emergent radical right parties fall into this category prior to experiencing their breakthrough. The only instance in our sample where a country saw the radical right fall into marginalization after breakthrough is Sweden in the early 1990s (New Democracy).
Breakthrough phase: The first time radical right parties exceed $5 \%$ of the vote in a national election marks the beginning of the breakthrough phase. Following their initial electoral breakthrough, parties remain in the breakthrough phase through the next two national elections. If they receive $5 \%$ of the vote in the two subsequent national elections, they move to the consolidation phase. If they fail to attract $5 \%$ of the vote in one or both of the two subsequent national elections, they go back to the marginalization phase.
Consolidation phase: Following Art (2011), we conceptualize consolidation as electoral persistence: The radical right in a given country can be viewed as consolidated once radical right parties receive at least $5 \%$ of the vote in at least three consecutive national elections.

Whenever existing parties that previously attracted more than $5 \%$ of the vote morphed into radical right parties through ideological transformations (e.g. the Austrian FPÖ from 1986, the Swiss SVP from the early 1990s, or the Norwegian FrP from 1987), we consider them to be in the breakthrough phase starting with the first election they competed as a radical right party. This yields the following classification displayed in Table 3.

- Time Trend: We test for a linear time trend in the effect of accommodative policy shifts by using election years as a moderator.
- Cordon sanitaire: Following Art (2011) and van Spanje (2018), we observe when mainstream parties erect cordons sanitaires against radical right challengers, that is, when they systematically rule out cooperation with radical right parties. We thus arrive at the coding scheme presented in Table 4 for the years in our sample.
- Competitive environment: For all mainstream party in our sample, we establish whether its immigration position on the log-odds scale is liberal $(<0)$ or restrictive $(\geq 0)$. For any given mainstream party, we then determine the most liberal and the most restrictive immigration policy positions held by its respective mainstream competitors (if the total number of mainstream parties is $\geq 3$ ) or the position held by its sole mainstream competitor (if the total number of mainstream parties is 2). Based on this information, we define the competitive environment that a given mainstream party faces as follows:
- Liberal when all other mainstream parties hold liberal positions on immigration policy (if the total number of mainstream parties is $\geq 3$ ) or when the

| Country | Marginalization | Breakthrough | Consolidation |
| :--- | :---: | :---: | :---: |

Table 3: Radical right life cycles by country.

| Country | No Cordon Sanitaire | Cordon Sanitaire |
| :--- | :---: | :---: |
| AT | $1990-2017$ | - |
| BE-VL | - | $1981-2010$ |
| BE-WA | - | $1987-2010$ |
| CH | $1991-2015$ | - |
| DE | - | $1987-2017$ |
| DK | $1979-2011$ | - |
| FI | $2003-2011$ | - |
| FR | - | $1978-2017$ |
| GB | - | $1987-2017$ |
| IT | $1983-2013$ | - |
| NL | $2002-2017$ | $1982-1998$ |
| NO | $1989-2013$ | - |
| SE | - | $1991-2014$ |

Table 4: Cordons sanitaires against radical right parties by country.
sole mainstream competitor holds a liberal position (if the total number of mainstream parties is 2 )

- Mixed when some mainstream competitors hold liberal positions and some mainstream competitors hold restrictive positions on immigration policy (only if the total number of mainstream parties is $\geq 3$ )
- Rightist when all other mainstream parties hold restrictive positions on immigration policy (if the total number of mainstream parties is $\geq 3$ ) or when the sole mainstream competitor holds a restrictive position (if the total number of mainstream parties is 2 )
- Party family: To test for heterogeneity in the effects of accommodative policy shifts between proximate and non-proximate mainstream parties, we subset our analyses to parties of the mainstream left (social democrats) and mainstream right (conservatives, christian democrats, and selected right-liberal parties: The Swiss FDP, the Danish V, and the Dutch VVD).
- Party system issue salience: We calculate the systemic salience of the immigration issue domain as a weighted average of the party-specific salience scores in a given electoral context (using each of the four measures described in Section B. 1 in turn), where parties' vote shares in the corresponding elections serve as weights.
- Past position: For parties' past positions on the immigration issue domain, we simply use parties' position scores from the previous election, $\operatorname{pos}_{p^{j t-1}}$ (using each of the four measures described in Section B. 1 in turn).

## B.3. Control Variables

- Vote shares $(t-1)$ : For every given mainstream party, we control for its size in the legislative cycle leading up to an election as well as for the (cumulative) size of its radical right competitors.
- Government status $(t-1)$ : For every mainstream party in the sample, we assign one of three categories that applies to the legislative cycle leading up to a given election:
- Opposition if the party was in opposition prior to the election.
- Government if the party was in government prior to the election.
- Government with RRP Participation if the party was part of a government that included, or was support by, radical right parties.
- Unemployment: To control for the macro-economic situation, we use unemployment rates provided by Teorell et al. (2019) and the International Labor Organization (2018). We control for levels at $t-1$ and changes from $t-1$ to $t$.
- Share of foreign population: In order to control for fluctuating migration rates, we add the share of foreign citizens - here, we extend data provided by Golder (2003) with more recent information from Eurostat (2018). We control for levels at $t-1$ and changes from $t-1$ to $t$.
- Moderators: Additionally, all models include the following variables: The radical right life cycle, cordon sanitaire, competitive environment (as an interaction effect of the most liberal and most restrictive positions), and party system issue salience.

Table 6: Summary statistics, micro-level study. Vote switching information based on post-imputation sample.

## D. Data Structure and Modeling Strategies

## Disaggregating Mainstream Parties

In our macro-level analyses, we replicate each outcome - changes in radical right vote shares - by the number of relevant mainstream parties in a given election. Consequently, outcomes do not vary within elections, and thus the explanatory power of our models stem from comparisons across electoral contexts. We use fractional frequency weights ${ }^{5}$ for stacked observations such that each stacked observation is weighted by the inverse number of times the outcome is replicated. For instance, in an electoral context with three mainstream parties (and thus three replications of the same outcome $Y_{i}$ ), each entry in the model's likelihood function will be weighted by $1 / 3$. This yields a (deterministic) mixture model. As opposed to treating one outcome (change in radical right vote share) to $100 \%$ as the outcome of a single data generating process - e.g.:

$$
\Delta \text { Vote Share }_{\text {FPÖ } 2017}=f\left(\Delta \text { Policy Strategy }_{\text {ÖVP } 2017}\right)
$$

we treat one observation as the outcome of three distinct data-generating processes (each reflecting the policy strategies of a single mainstream party) to $33.3 \%$ each, e.g.:

$$
\left.\begin{array}{rl}
\Delta \text { Vote Share }_{\text {FPÖ } 2017}= & 0.33 \times f\left(\Delta \text { Policy Strategy }_{\text {ÖVP } 2017}\right) \\
& +0.33 \times f(\Delta \text { Policy Strategy } \\
& +0.33 \times f(\Delta \text { Policy Strategy } \\
\text { SPÖ 2017 }
\end{array}\right)
$$

As a result of the use of these fractional frequency weights, the weights strictly sum to $\sum_{i=1}^{N} w_{i}=108$, which means that even though we use information from 351 observations, the number of effective entries in the likelihood sums to 108 , where each radical right vote share change, although explained by a mixture of several data generating processes, has a weight of exactly one. Additionally, we use election-clustered standard errors to account for dependencies among observations from the same electoral context.

The benefit of this approach is that it allows to study the effects of party strategies for any number of mainstream parties competing with the radical right at the same time. This is particularly useful for contexts of fragmented party systems which defy the logic of 'triangular' party competition (see Oesch and Rennwald 2018). Our approach thus generalizes the standard model in which radical right success is modeled as the function of one mainstream competitor's strategy by pooling across all relevant mainstream parties in a given electoral context. We then implement more refined approaches focusing on party system configurations (e.g., Meguid 2005) by conditioning each parties' policies on its competitive environment.
The benefits of disaggregating mainstream parties are even more pronounced in our micro-level analyses. Here, our quantity of interest are aggregate dyadic losses, gains, and net transfers between a given mainstream party and the radical right. These aggregatelevel quantities of interest are estimated via party-election random intercepts in hierarchi-

[^0]cal linear models. Importantly, these are genuinely dyadic quantities - they are different for each radical right-mainstream party dyad in a given electoral context.
For illustration, consider the following voter transition matrix from the Austrian National Election Study 2017, which shows vote choices across six categories - the centerleft SPÖ, the liberal NEOS, the center-right ÖVP, the radical right FPÖ, as well as other parties and non-voters across the two consecutive elections of 2013 (rows) and 2017 (columns):

|  | SPÖ | NEOS | ÖVP | OTH | FPÖ | NON |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| SPÖ | 196 | 10 | 33 | 29 | 44 | 15 |
| NEOS | 0 | 16 | 26 | 5 | 3 | 3 |
| ÖVP | 6 | 6 | 210 | 2 | 30 | 6 |
| OTH | 37 | 11 | 25 | 73 | 9 | 9 |
| FPÖ | 3 | 4 | 59 | 4 | 97 | 5 |
| NON | 34 | 13 | 42 | 20 | 32 | 49 |

Now, consider dyadic voter transfers between the SPÖ and the FPÖ:

- 44 respondents who voted for the SPÖ in 2013 voted for the FPÖ in 2017 (3.7\% of the sample); the FPÖ's aggregate gross gains from the SPÖ are thus 0.037
- 3 respondents who voted for FPÖ in 2013 voted for the SPÖ in 2017 ( $0.2 \%$ of the sample); the FPÖ's aggregate gross losses to the SPÖ are thus 0.002
- As a corollary, the FPÖ's net transfers with the SPÖ are $0.037-0.002=+0.035$, a dyadic net gain of 3.5 percentage points

The FPÖ's dyadic voter transfers with the ÖVP, of course, look very different:

- 30 respondents who voted for the ÖVP in 2013 voted for the FPÖ in 2017 ( $2.6 \%$ of the sample); the FPÖ's gross gains from the ÖVP are thus 0.026
- 59 respondents who voted for FPÖ in 2013 voted for the ÖVP in 2017 ( $5.1 \%$ of the sample); the FPÖ's gross losses to the ÖVP are thus 0.051
- As a corollary, the FPÖ's net transfers with the ÖVP are $0.025-0.051=-0.026$, a net loss of 2.6 percentage points

Lastly, the FPÖ's dyadic voter transfers with the NEOS would yet again be different. As dyadic quantities, aggregate losses, gains, and net transfers thus require a stacking by mainstream parties; otherwise, they could not be estimated for each unique dyad. This explains why our vote switching models involve $J=228$ mainstream-radical right dyads and not simply 108 radical right parties.
The circumstance that the lowest level of our hierarchical models features $\sum_{j=1}^{J} N_{j} \approx$ 468,000 observations (i.e., the sum of survey respondents across all party dyads) follows the standard logic of hierarchical/multi-level modeling: A mainstream parties' gross gains, gross losses, and net transfers with the radical right are not fixed quantities that we can simply observe (like vote shares), but estimates that need to be retrieved from survey data. We estimate these quantities per random intercepts in hierarchical linear
models. The intercepts at the level of the $J=228$ election-specific mainstream-radical right dyads capture the aggregate quantities of interest - dyadic gross gains, gross losses, and net transfers on the basis of many respondents in the corresponding electoral context. Running such a hierarchical model on the 468,000 level- 1 observations is superior to simply running an aggregate-level model on the 228 pre-calculated means of these dyadic net transfers, as the uncertainty involved in the aggregation from the lower to the upper level is considered in the estimation of the upper-level model. As such, our modeling strategy is more statistically principled than a naive two-step estimation.

## Pooling Radical Right Parties

In some electoral contexts, multiple radical right parties compete at the same time, though usually at most one radical right party manages to achieve notable records of electoral success. We deliberately choose not to treat each radical right parties' success as an outcome of its own. Instead of analyzing the effect of a given mainstream party's strategy separately for two radical right challengers, we thus pool the success of 'the radical right' and treat it as one observation.
We make this choice because disaggregating (changes in) radical right vote shares across multiple parties can lead to highly misleading inferences. Consider the following example with two mainstream parties, A and B, and two radical right parties, M and N. Suppose A maintains a centrist position on immigration whereas B shifts two points to the right. M maintains a low level of support at $2 \%$ of the vote whereas N , a new party, goes from $0 \%$ to $12 \%$. Following our approach, one would conclude that the average shift of one point two the right coincides with an increase in radical right vote shares of 12 percentage points, which we believe to be an accurate characterization of the observed pattern.

Alternatives where each radical party were treated as an observation of its own, however, may result in drastically different inferences. A regression of changes in vote shares on policy shifts, for instance, would produce an estimate of half the size, averaging across vote share changes of 0 and 12 percentage points. In a more drastic form where not one, but three marginal radical right parties maintained their vote share, the estimate would drop to a quarter of its original magnitude. A fixed effects approach, regressing withindemeaned levels in vote shares on within-demeaned policy positions, would produce even more misleading results: As A's position would be a unit above, and B's position a unit below the average position while M's vote share would be five percentage points above and N's five percentage points below the national average, the resulting estimate would be zero.
We thus opt for an approach that pools radical right parties' success and relies explicitly on changes in radical right vote shares and party positions. This also mirrors the logic of our micro-level analyses of vote switching as closely as possible. As a consequence of this modeling strategy, we also need to capture predictors specific to multiple individual radical right parties - specifically, cordon sanitaires and radical right life cycles - at the election-level. For cordon sanitaires, we choose to focus on the largest radical right party. This is because larger parties are arithmetically more important for prospective government formation and its chances of joining government are likely most important in conditioning electoral responses to mainstream party policy strategies on immigration. For radical right life cycles, we consider path dependencies within party systems. Take the Dutch LPF, for instance. After its thunderous breakthrough in 2002, the party only maintained a vote shares of barely over $5 \%$ in the 2003 election (and ultimately imploded in the 2006 election). Yet, Geert Wilders' newly founded PVV attracted a sizable vote
share in 2006, following directly in the LPF's footsteps and actively learning from its failures (see, e.g., Art 2011; de Lange and Art 2011). Therefore, even though 2012 marked the first time one and the same radical right party maintained a vote share of at least $5 \%$ in three consecutive elections, we consider the 2006 election in which the radical right passed this criterion, and thus consider 2006 the end of the breakthrough phase for the Dutch radical right.

Table 10: Estimates and $95 \%$ confidence intervals for panel 2 of Fig. 2 based on $S=5000$ simulations from $M=5$ imputations.

## F. Robustness Checks

## F.1. Alternative Measures

Measure 1: National Identity

Figure 1: Reprint of Fig. 2, which uses the "National Identity" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 2: Anti-Multiculturalism

Figure 2: Robustness check using the "Multiculturalism" measure described in Section B.1. Marginal effects with 95\% confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

## Measure 3: Immigration

Figure 3: Robustness check using the "Immigration" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 4: Cultural Protectionism \& Traditional Morality

Figure 4: Robustness check using the "Cultural Protectionism \& Traditional Morality" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

## F.2. Jackknifing across Alternative Measures (Macro)

## Measure 1: National Identity

Figure 5: Jackknifing by countries using the "National Identity" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Figure 6: Jackknifing by elections using the "National Identity" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 2: Anti-Multiculturalism

Figure 7: Jackknifing by countries using the "Multiculturalism" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Figure 8: Jackknifing by elections using the "Multiculturalism" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 3: Immigration

Figure 9: Jackknifing by countries using the "Immigration" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Figure 10: Jackknifing by elections using the "Immigration" measure described in Section B.1. Marginal effects with 95\% confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 4: Cultural Protectionism \& Traditional Morality

Figure 11: Jackknifing by countries using the "Cultural Protectionism \& Traditional Morality" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Figure 12: Jackknifing by elections using the "Cultural Protectionism © Traditional Morality" measure described in Section B.1. Marginal effects with 95\% confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

## F.3. Macro-level Findings Replicated on Subsample of the Micro-level Analysis

## Measure 1: National Identity

Figure 13: Robustness check of the first column of Fig. 2. Estimated on the same subsample as the micro-level study (70 elections, 228 mainstream parties) and using the "National Identity" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

## Measure 2: Anti-Multiculturalism

Figure 14: Robustness check of the first column of Fig. 2. Estimated on the same subsample as the micro-level study (70 elections, 228 mainstream parties) and using the "Multiculturalism" measure described in Section B.1. Marginal effects with 95\% confidence intervals.

## Measure 3: Immigration

Figure 15: Robustness check of the first column of Fig. 2. Estimated on the same subsample as the micro-level study (70 elections, 228 mainstream parties) and using the "Immigration" measure described in Section B.1. Marginal effects with 95\% confidence intervals.

Measure 4: Cultural Protectionism \& Traditional Morality

Figure 16: Robustness check of the first column of Fig. 2. Estimated on the same subsample as the micro-level study (70 elections, 228 mainstream parties) and using the "Cultural Protectionism \&3 Traditional Morality" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

## F.4. Replication with Control for Public Opinion

## Measure 1: National Identity

Figure 17: Robustness check of the first column of Fig. 2. Estimated with control for public opinion on immigration (Caughey, O'Grady, and Warshaw 2019) and using the "National Identity" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

## Measure 2: Anti-Multiculturalism

Figure 18: Robustness check of the first column of Fig. 2. Estimated with control for public opinion on immigration (Caughey, O'Grady, and Warshaw 2019) and using the "Multiculturalism" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

## Measure 3: Immigration

Legend
Baseline Specification

(11) Mainstream Left

Competitive Environment (Immigration)
(12) Restrictive
(13) Mixed
(14) Liberal

Party System Issue Salience (Immigration)
(15) Low (10th percentile)
(16) Medium (50th percentile)
(17) High (90th percentile)

Past Position (Immigration)
(18) Liberal (10th percentile)
(19) Centrist (50th percentile)
(19) Centrist (50th percentile)
(20) Restrictive (90th percentile)

Figure 19: Robustness check of the first column of Fig. 2. Estimated with control for public opinion on immigration (Caughey, O'Grady, and Warshaw 2019) and using the "Immigration" measure described in Section B.1. Marginal effects with 95\% confidence intervals.

Measure 4: Cultural Protectionism \& Traditional Morality

Figure 20: Robustness check of the first column of Fig. 2. Estimated with control for public opinion on immigration (Caughey, O'Grady, and Warshaw 2019) and using the "Cultural Protectionism ${ }^{8}$ Traditional Morality" measure described in Section B.1. Marginal effects with 95\% confidence intervals.

## F.5. Average Mainstream Party Shifts

Note: This test looks at the average position shifts of all mainstream parties in a given electoral context. The units of analysis are thus elections, not party-elections. We therefore exclude all conditional specifications that involved interactions with mainstream party characteristics, i.e., the position previously held by each mainstream party, the competitive environment from the perspective of each mainstream party, and the mainstream right/left subsets.

## Measure 1: National Identity

Figure 21: Robustness check of the first column of Fig. 2. Estimated with average shifts and positions of all mainstream parties contesting the respective elections and using the "National Identity" measure described in Section B.1. Party-specific controls and interaction terms not included. Marginal effects with $95 \%$ confidence intervals.

## Measure 2: Anti-Multiculturalism

Figure 22: Robustness check of the first column of Fig. 2. Estimated with average shifts and positions of all mainstream parties contesting the respective elections and using the "Multiculturalism" measure described in Section B.1. Party-specific controls and interaction terms not included. Marginal effects with $95 \%$ confidence intervals.

## Measure 3: Immigration

Figure 23: Robustness check of the first column of Fig. 2. Estimated with average shifts and positions of all mainstream parties contesting the respective elections and using the "Immigration" measure described in Section B.1. Party-specific controls and interaction terms not included. Marginal effects with $95 \%$ confidence intervals.

Measure 4: Cultural Protectionism \& Traditional Morality

Figure 24: Robustness check of the first column of Fig. 2. Estimated with average shifts and positions of all mainstream parties contesting the respective elections and using the "Cultural Protectionism \& Traditional Morality" measure described in Section B.1. Party-specific controls and interaction terms not included. Marginal effects with $95 \%$ confidence intervals.

## F.6. Replication with Main RRP Only

Note: Instead of pooling all available radical right parties within a given electoral context, this test uses the change in vote shares (macro-level) and voter transfer data (micro-level) for the electorally strongest radical right party only.

## Measure 1: National Identity

| Legend |

Figure 25: Robustness check of the first column of Fig. 2. Based on vote share change and voter transfer data for the strongest radical right party within each electoral context, using the "National Identity" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

## Measure 2: Anti-Multiculturalism

Figure 26: Robustness check of the first column of Fig. 2. Based on vote share change and voter transfer data for the strongest radical right party within each electoral context, using the "Multiculturalism" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

## Measure 3: Immigration

Figure 27: Robustness check of the first column of Fig. 2.Based on vote share change and voter transfer data for the strongest radical right party within each electoral context, using the "Immigration" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

Measure 4: Cultural Protectionism \& Traditional Morality

Figure 28: Robustness check of the first column of Fig. 2. Based on vote share change and voter transfer data for the strongest radical right party within each electoral context, using the "Cultural Protectionism \& Traditional Morality" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals.

## F.7. Replication across 1000 Random Subsets using One Mainstream Party Per Election at a Time

Note: Instead of stacking mainstream parties and applying fractional frequency weights to adjust for the replication of identical outcomes, these specifications explain the 108 unique changes in radical right vote shares as a function of the policy shifts of exactly one mainstream party per election. This is repeated across $S=1000$ random samples, each composed of a different selection of one mainstream party per electoral context. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 1: National Identity

Figure 29: Robustness check of the first column of Fig. 2. Regression of the 108 unique changes in radical right vote shares as a function of the policy shifts of exactly one mainstream party per election, repeated across $S=1000$ random selections of one mainstream party per electoral context. Uses the "National Identity" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

## Measure 2: Anti-Multiculturalism

Figure 30: Robustness check of the first column of Fig. 2. Regression of the 108 unique changes in radical right vote shares as a function of the policy shifts of exactly one mainstream party per election, repeated across $S=1000$ random selections of one mainstream party per electoral context. Uses the "Multiculturalism" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 3: Immigration

Figure 31: Robustness check of the first column of Fig. 2. Regression of the 108 unique changes in radical right vote shares as a function of the policy shifts of exactly one mainstream party per election, repeated across $S=1000$ random selections of one mainstream party per electoral context. Uses the "Immigration" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

Measure 4: Cultural Protectionism \& Traditional Morality

Figure 32: Robustness check of the first column of Fig. 2. Regression of the 108 unique changes in radical right vote shares as a function of the policy shifts of exactly one mainstream party per election, repeated across $S=1000$ random selections of one mainstream party per electoral context. Uses the "Cultural Protectionism \& Traditional Morality" measure described in Section B.1. Marginal effects with $95 \%$ confidence intervals. Statistically insignificant estimates are represented in gray, statistically significant estimates are shown in black.

[^0]:    5. We do so using Stata's iweight option, one of the few pre-implemented software solutions that allows for the use of genuine fractional frequency weights (as opposed to relative/analytical weights). However, users can also use the more widespread relative/analytical weights along with clustered standard errors that adjust for the stacking of observations within electoral contexts to produce virtually identical results.
